Comprehensive Atmospheric Monitoring Programme:

**Pollutant deposits and air quality around
the North Sea and the North-East Atlantic
in 2005**

**OSPAR Commission
2007**

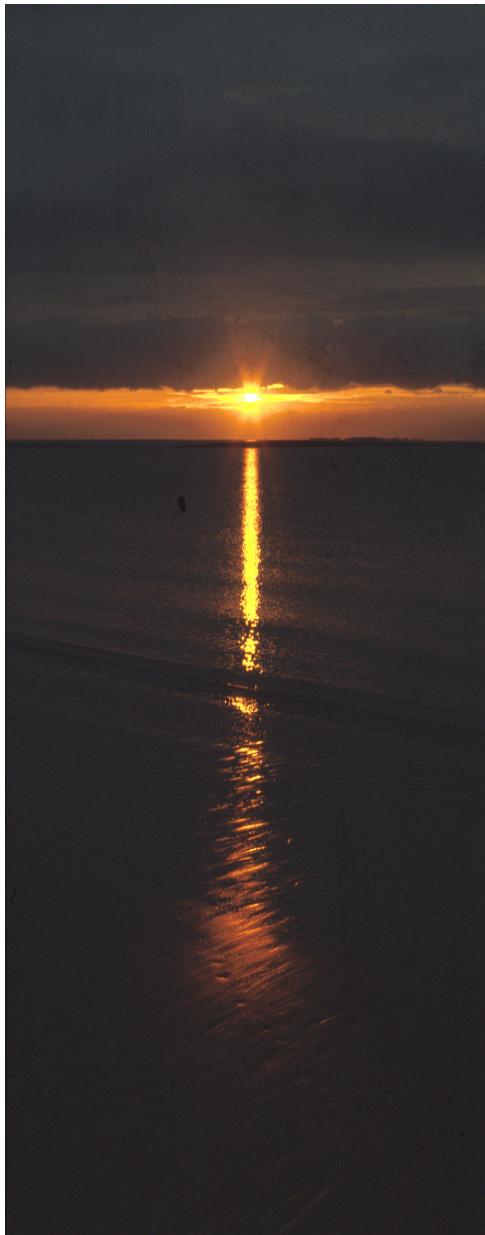

The Convention for the Protection of the Marine Environment of the North-East Atlantic (the “OSPAR Convention”) was opened for signature at the Ministerial Meeting of the former Oslo and Paris Commissions in Paris on 22 September 1992. The Convention entered into force on 25 March 1998. It has been ratified by Belgium, Denmark, Finland, France, Germany, Iceland, Ireland, Luxembourg, Netherlands, Norway, Portugal, Sweden, Switzerland and the United Kingdom and approved by the European Community and Spain.

La Convention pour la protection du milieu marin de l'Atlantique du Nord-Est, dite Convention OSPAR, a été ouverte à la signature à la réunion ministérielle des anciennes Commissions d'Oslo et de Paris, à Paris le 22 septembre 1992. La Convention est entrée en vigueur le 25 mars 1998. La Convention a été ratifiée par l'Allemagne, la Belgique, le Danemark, la Finlande, la France, l'Irlande, l'Islande, le Luxembourg, la Norvège, les Pays-Bas, le Portugal, le Royaume-Uni de Grande Bretagne et d'Irlande du Nord, la Suède et la Suisse et approuvée par la Communauté européenne et l'Espagne.

Executive Summary / Récapitulatif

This report presents the results of monitoring undertaken by OSPAR Contracting Parties for the Comprehensive Atmospheric Monitoring Programme (CAMP) during 2005. Under the CAMP, OSPAR Contracting Parties are committed to monitoring, on a mandatory basis, the concentrations of a range of heavy metals, organic compounds and nutrients in precipitation and air, and their depositions. The CAMP encourages OSPAR Contracting Parties to monitor, on a voluntary basis, additional compounds (such as certain persistent organic pollutants). The report gives detailed information on atmospheric inputs of selected contaminants to the OSPAR maritime area and its regions.

Le présent rapport comporte les résultats de la surveillance continue effectuée par les Parties contractantes OSPAR, en 2005, dans le cadre du Programme exhaustif de surveillance continue de l'atmosphère (CAMP). Les Parties contractantes OSPAR sont tenues de surveiller obligatoirement les teneurs de toute une gamme de métaux lourds, de composés organiques et de nutriments dans les précipitations et l'atmosphère, ainsi que leurs retombées, ceci dans le cadre du CAMP. Celui-ci encourage les Parties contractantes OSPAR à surveiller de manière facultative des composés supplémentaires (tels que les polluants organiques persistants). Le rapport fournit des informations détaillées sur les apports atmosphériques de contaminants sélectionnés à la zone maritime OSPAR et à ses régions.

Overall, reporting in 2005 has remained at a reasonably high level, with over 80% achievement of the mandatory monitoring of contaminants over the last two years. This said, there is some tendency not to report particular substances subject to mandatory monitoring, such as mercury and lindane. There is also a lesser tendency to follow the programme for airborne pollutants than the programme for components in precipitation. These features may reflect the interests of Contracting Parties, and may be an issue for consideration.

Dans l'ensemble, la notification se maintient à un niveau élevé raisonnable en 2005. La surveillance obligatoire des contaminants durant les deux dernières années a dépassé 80%. Ceci étant, on tend à ne pas notifier certaines substances dont la surveillance est obligatoire, telles que le mercure et le lindane. On tend également, mais dans une moindre mesure, à suivre le programme pour les polluants atmosphériques plutôt que le programme pour les paramètres dans les précipitations. Ceci pourrait refléter les préférences des Parties contractantes et pourrait constituer une question à étudier.

The reported data show that depositions of most pollutants subject to mandatory monitoring have declined since 2000. The slight increase since 2004 may well be due simply to varying meteorological conditions; no assessment of this has been undertaken. The one pollutant which has not shown a decline since 2000 is mercury.

Les données notifiées révèlent que les retombées de la plupart des polluants, qui font l'objet d'une surveillance obligatoire, ont diminué depuis 2000. La légère augmentation que l'on a notée depuis 2004 pourrait être liée simplement à des conditions météorologique variables. Ceci n'a pas fait l'objet d'une évaluation. Le mercure est le seul polluant qui n'a pas diminué depuis 2000.

The nutrients nitrate and ammonium show expected spring time peaks in their deposition to both North Sea and wider North-East Atlantic waters. As may be expected, ammonium deposition gradients are sharper than those for nitrate, particularly in the North Sea. This reflects both the different transport characteristics for these pollutants and the sharper peak in expected emissions of ammonium in spring.

Les retombées de nutriments, nitrate et ammonium, aussi bien dans la mer du Nord que dans les eaux de l'Atlantique du Nord-est au sens large, révèlent des maximums prévus au printemps. Comme l'on peut s'y attendre, les gradients de retombées d'ammonium sont plus abrupts que ceux du nitrate, en particulier dans la mer du Nord. Ceci reflète à la fois les diverses caractéristiques du transport de ces polluants et le maximum plus abrupt des émissions d'ammonium prévues au printemps.

1. Introduction

This report describes the reports from coastal monitoring stations across the OSPAR region (see Figure 1.1) under the Comprehensive Atmospheric Monitoring Programme (CAMP).

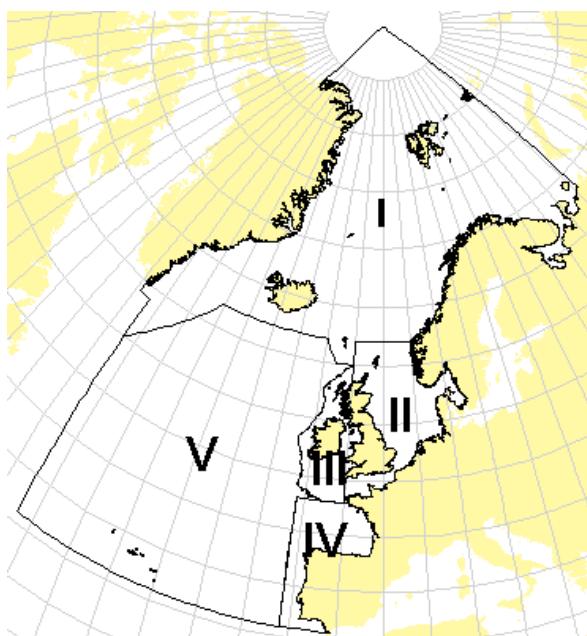

Figure 1.1: OSPAR maritime area and regions I: Arctic waters, II: Greater North Sea, III: Celtic Seas, IV: Bay of Biscay, V: Wider Atlantic

The Comprehensive Atmospheric Monitoring Programme forms one element within the wider Joint Assessment and Monitoring Programme of OSPAR. The CAMP aims to assess, as accurately as appropriate, the atmospheric input of the selected contaminants to the OSPAR maritime area and regions thereof (Figure 1.1) on an annual basis through monitoring the concentrations of selected contaminants in precipitation and air, and determining their deposition. The monitoring regime employed is set out in the CAMP Principles (OSPAR reference number: 2001-7), describing the relevant substances, sampling approach, locations and frequency, and assessment methodologies.

The components of interest to the CAMP are divided into two groups, for measurement on a mandatory basis and for measurement on a voluntary basis. These are listed in Table 1.1.

Table 1.1: Components to be measured under the CAMP

	Mandatory	Voluntary
Precipitation	As, Cd, Cr, Cu, Pb, Hg, Ni, Zn, γ -HCH, NH_4^+ , NO_3^-	PCB 28,52,101,118,138,153,180 PAHs: Phenanthrene, anthracene, fluoranthene, pyrene, benzo(a)anthracene, chrysene, benzo(a)pyrene, benzo(ghi)perylene, indeno(1,2,3-cd)pyrene
Airborne	NO_2 , HNO_3 , NH_3 , NH_4^{+a} , NO_3^{-a}	As, Cd, Cr, Cu, Pb, Hg, Ni, Zn, γ -HCH, PCB 28,52,101,118,138,153,180, PAHs: Phenanthrene, anthracene, fluoranthene, pyrene, benzo(a)anthracene, chrysene, benzo(a)pyrene, benzo(ghi)perylene, indeno(1,2,3-cd)pyrene, NO

^a) total ammonium ($\text{NH}_3 + \text{NH}_4^+$) and total nitrate ($\text{HNO}_3 + \text{NO}_3^-$) is an alternative

The CAMP Principles call for each Contracting Party bordering the OSPAR maritime area (excluding the EU) to operate at least one monitoring station on the coast and/or offshore as part of the CAMP. Where Parties border more than one region (see Figure 1.1) at least one station should be operating in each. These stations should be so-called background stations, i.e. not directly influenced by local emission sources. The stations should be located not more than 10 km from the coastline.

The data assembled by monitoring stations are reported by Contracting Parties to the Norwegian Institute for Air Research (NILU) on a yearly basis, using a reporting format and according to the time schedule set out in the CAMP Principles. Based on the data received, NILU prepares a CAMP data report on an annual basis for OSPAR to examine.

The present CAMP data report “Pollutant depositions and air quality around the North Sea and the North-East Atlantic in 2005” gives in chapter 2 an overview of reported data and the implementation of the CAMP Principles in 2005. The geographical coverage, the contaminants which have been monitored on a mandatory and voluntary basis, and the timeliness of data submission are presented. In chapter 3, an overview is given of the 2005 annual average values of the components subject to mandatory monitoring for the North-East Atlantic. In chapter 4, the deposition of nitrogen to the Atlantic coastline and the North Sea in 2005 has been calculated employing the “Method 3a” as laid down in the CAMP Principles. Chapter 5 addresses data uncertainty and presents the detection limits achieved by Contracting Parties. Chapter 6 summarises the report’s observations on the reported CAMP data for 2005. The data submitted by Contracting Parties are appended to this report (Appendix 1).

2. The OSPAR CAMP Monitoring Programme in 2005

2.1 Geographical coverage

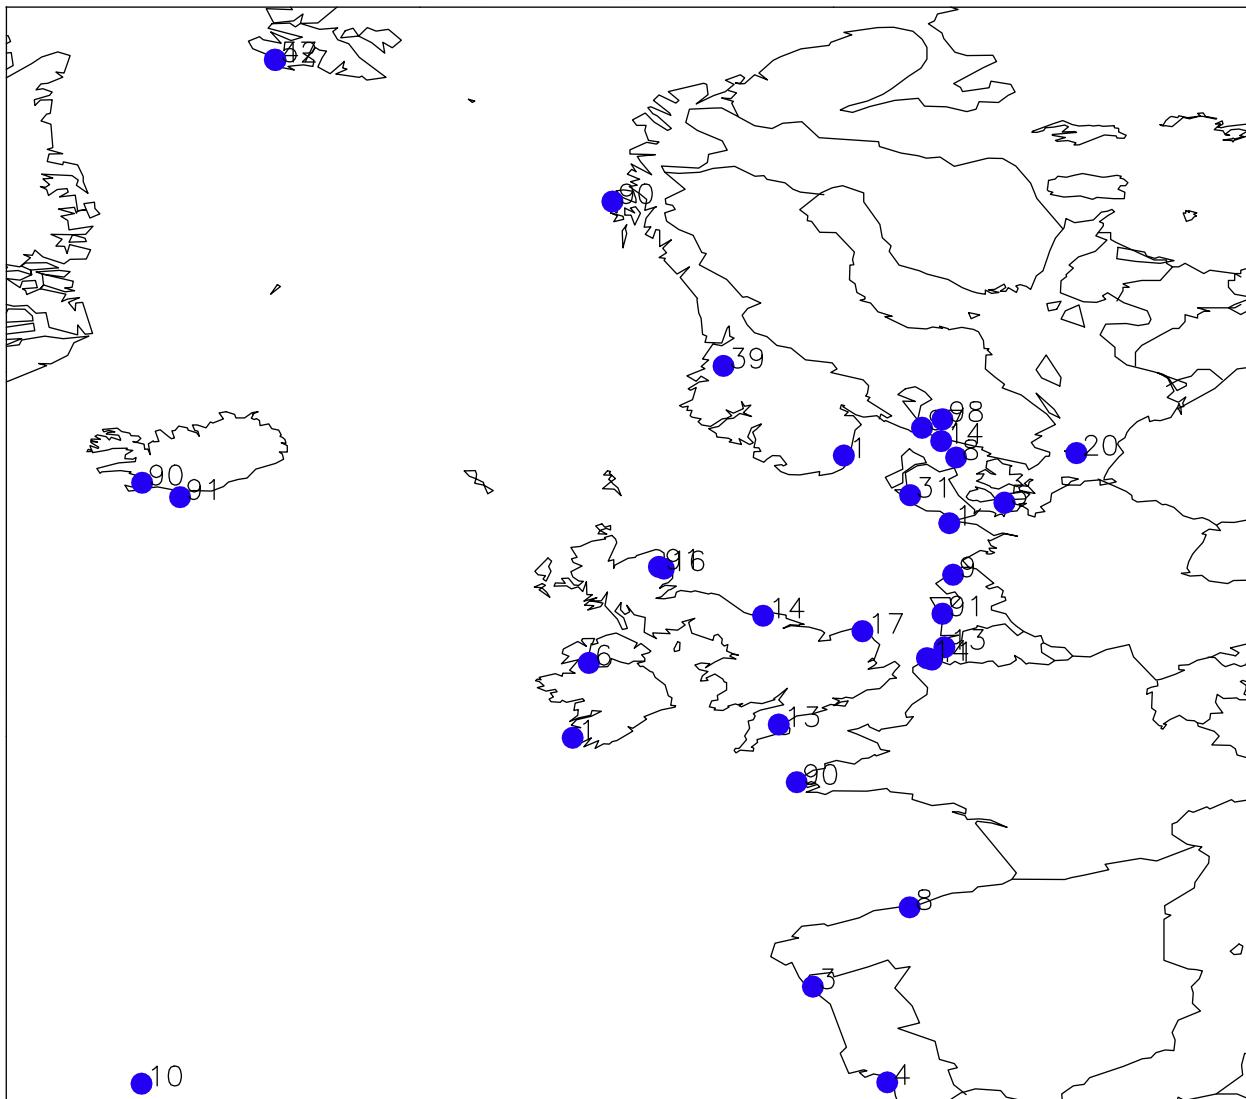

Figure 2.1: Monitoring sites reporting to OSPAR. Station numbers are the station numbers listed in table 2.1 without the country letters.

Known changes to the reporting network during 2005 were small, with observations now being reported from Andøya. This improves surveillance of inputs to Arctic waters, and addresses the observation from the CAMP 2004 Data Report (OSPAR publication 289/2006) which commented that monitoring in northern regions was dispersed. Table 2.1 details monitoring stations, and indicates the monitoring undertaken: observation of the deposition of pollutants in precipitation (p), and/or monitoring of ambient air quality (a). Not all stations reported data for all components.

Table 2.1: Stations reporting precipitation and air quality to OSPAR in 2005

2.2 Completion of the observation programmes

The Comprehensive Atmospheric Monitoring Programme (CAMP) can provide ground truth data on atmospheric pollution of OSPAR waters in a coordinated and geographically appropriate manner. Full observance of the mandatory monitoring of components, for both precipitation and airborne contaminants, was made by Germany, Norway and Sweden. Together with Belgium these three followed the mandatory programme for components in precipitation. The mandatory programme for airborne contaminants was observed by the three together with Denmark, Netherlands, Spain and the UK. The least reported contaminants are mercury (6 reporting, unchanged since 2003) and lindane (6 reporting, unchanged since 2003). Two Contracting Parties, France and Ireland, chose not to report any mandatory air components. From combined numbers of Contracting Parties and pollutants, the percentage observance of the mandatory contaminant monitoring has risen from 78% in 2003, to 83% in both 2004 and 2005.

Table 2.2: Mandatory monitoring of contaminants in precipitation for 2005*:

For the first time this year, the degree of successful completion of the CAMP programme expressed as a percentage has been attempted. The results are shown in table 2.4 based on the assumption that full completion of the programme would be represented by delivery of 12 monthly averages for each of the listed components. The mandatory monitoring of components in precipitation under CAMP, for example, comprises 11 substances, so that 11×12 month averages would be needed to achieve 100% delivery. For airborne components there is an optional approach to monitoring nitrogen compounds, and the estimates in table 2.4 assume the minimum approach, i.e. that combined NH₃+NH₄ sampling is sufficient, as is combined NO₃+HNO₃. Where a Party monitors separate compounds, the full complement must then be monitored to achieve 100%. A weakness is that no credit is given for monitoring at more than one site. As a final column, the table also gives the number of additional compounds being reported, i.e. compounds additional to the requirements of either the Mandatory or the Voluntary lists.

* Grey boxes in Tables 2.2 and 2.3 indicate contaminants for which no data were reported.

Table 2.4: Percentage completion of the CAMP programme.

	Precipitation		Airborne		
	Mandatory	Voluntary	Mandatory	Voluntary	no. Extra
Belgium	90,9	0	33,3	19,9	9
Denmark	81,8	0	97,2	38,7	4
France	83,3	0	0	0	0
Germany	100	93,8	100	19,2	15

Sweden	99,2	0	100	39,1	3
United Kingdom	97,5	0	100	96,2	0

2.3 Timeliness of reporting

The reporting of data for observations for the year 2005 was close to accordance with the time schedule of the CAMP Principles (see Table 2.5). Ten of twelve Contracting Parties reported according to schedule with an eleventh doing so in time for the data validation round. Only one was unable to deliver until after INPUT. Not all Parties delivered all data at their first delivery. Data received too late for reporting to INPUT could not be reviewed by that body. In one case (UK) the option of delivering data via the European Environment Agency's Data Exchange Module (DEM) was taken in good time, thus reducing the workload upon that Party. Unfortunately, difficulties at the EEA prevented this data being forwarded to NILU in the proper manner before INPUT. The UK subsequently resubmitted directly to NILU. This matter is being pursued at the EEA by the CAMP Data Manager. Table 2.6 gives an overview of the actual receipt of national observation reports.

Table 2.5 Timetable for data reporting according to the CAMP Principles

30 th June	Call for metadata and data issued from NILU (regarding new data and metadata), with instructions and reference to supporting software (e.g. where to find tools on the NILU website).
30 th September	Participants submit data and metadata via email or on diskette, in specified formats.
31 st October	NILU returns data and metadata via email or on diskette in the form of a 'validation report' to data originators for verification and signing off by the data originators within two weeks of reception.

March 2007 – Draft Report delivery to OSPAR for ASMO	

2.4 Reporting of additional components

Parties report a wider range of components than is covered by CAMP. This data is managed and stored by the Data Manager in the same way as for the regular data. Table 2.7 lists all components reported by Contracting Parties during 2005 (excluding major ions submitted for quality control, and components of no clear relevance to CAMP). These are colour-coded to indicate their status as mandatory components (green), voluntary components (blue) or additional components (red), and are listed with the country code of Parties concerned.

In the main body of this report describes the observations of the mandatory components alone. These are both tabulated and shown as maps. In the Appendices all observations from each country are listed, covering the mandatory components, the voluntary components, and any additional components. Excluded are only the major ions which are reported solely to provide the potential for quality control, and compounds which are a part of other international programmes but which may be expected to lie outside the core interest of OSPAR, e.g. sulphates, ozone, PM measurements.

3. Observed pollutant depositions at monitoring stations in 2005

This section describes air pollutant status at coastal stations around the North-East Atlantic in 2005. The annual average concentrations of contaminants subject to mandatory monitoring are listed and mapped, and deposition rates are tabulated. Full sea deposition estimates from observations are supplied in section 4. Heavy metal concentrations and depositions in precipitation are presented in Tables 3.1-2 and illustrated in Figures 3.1-3.7. Data for mercury is in Table 3.3 and Figure 3.8, and lindane in Table 3.4 and Figure 3.9. Nitrogen concentrations and depositions in precipitation are in Table 3.5, and are mapped in Figures 3.10-11. Colour coding highlights the two highest concentration/deposition, and the lowest concentration/deposition per pollutant.

3.1 Heavy metals (except mercury)

Some patterns are observable. Low pollutant levels at GB0006 are not unexpected on the western coast of Northern Ireland. High arsenic at GB0013 despite remote location reflects south-west England as an 18th century centre of metal mining, arsenic contamination being widespread. Extremes on Iceland reflect geothermal activity in a remote location. High values on the Iberian peninsula are less easily explained. Consistent high cadmium concentrations at Portuguese sites suggests an artifact. High observations at the Spanish site ES0008 are unexplained.

Table 3.1: Reported mean annual concentrations of heavy metals in precipitation (mg/l).

		arsenic µg/l	cadmium µg/l	chromium µg/l	copper µg/l	lead µg/l		zinc µg/l	precipitation mm

3.2 Mercury

The broad comparison in observed concentrations and depositions around the southern North Sea, from Norway around the coast to the United Kingdom, provides some reassurance as to the quality of these measurements. The basis, if there is any, for the slight division into two groups – Netherlands, Norway and Belgium, and Sweden, Germany and the UK – is not immediately apparent. Much higher reported concentrations for western Ireland would appear to reflect analytical limitations. This difficulty, together with the absence of any observations by Parties outside the North Sea basin, precludes identification of levels elsewhere across the OSPAR area.

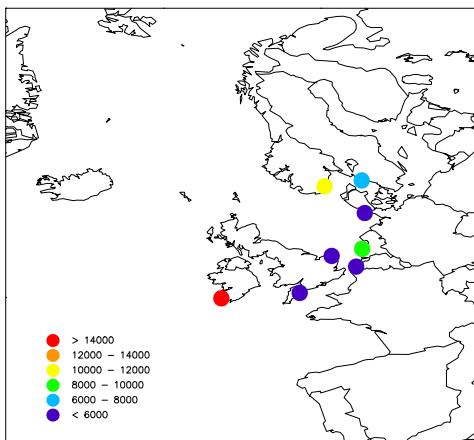

Figure 3.8: Mercury depositions 2005, $\text{ng}/\text{m}^2 \text{ p.a.}$

3.3 Lindane

Icelandic observations are very low in accordance with no local use and restricted distant transport. Values from Norway, Sweden and Germany are broadly comparable, although the factor of 3 difference between Sweden and the others should be evaluated. The observed depositions on the Dutch and Belgian coasts should also be evaluated. These are an order of magnitude greater than Swedish observations, which would be unexpected at such distance. Reported change since 2004 is unlikely, given the negative pattern in neighbouring countries. Depositions in Iceland, Sweden and Germany fell by ~15%, and in Norway slightly. Dutch consistency seems to indicate the detection limits achieved. The increase in depositions of nearly 50% on the Belgian coast is unexplained.

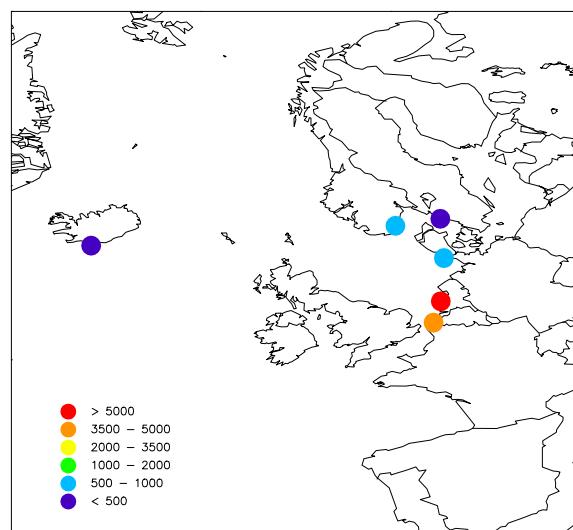

Figure 3.9: Lindane depositions 2005 ng/m²

4. Estimated total North Sea depositions and temporal patterns

4.1 Total North Sea depositions

OSPAR has previously estimated pollutant loadings to the North Sea on the basis of known relationships with observed pollutant concentrations at CAMP monitoring stations. This approach, known as 'Method 3a', applies transfer coefficients to observed pollutant concentrations to estimate total wet plus dry basin deposition*. The physical and chemical factors behind atmospheric transfer are inherent in the estimated transfer functions calculated from reported data rather than being explicitly described. Combining estimates derived from several stations around the sea provides balance against overweighting from any single unusual measurement. The approach is described in *Calculation of atmospheric inputs of contaminants to the North Sea 1987-92*, Oslo and Paris Commission (1994), Assessment and Monitoring Series, OSPAR publication 1994/25.

The approach is suited to estimating change. In this section both the absolute estimates of deposition in 2005 of nitrogen and metal components subject mandatory monitoring for precipitation in 2004 and 2005 are given (Table 4.1), and the proportional change since 2000 is presented (Figure 4.1).

Table 4.1: Estimated total annual depositions to the North Sea basin in 2004 and 2005, derived from measurements ('Method 3a'). Metals as tonnes per year, nitrogen as ktonnes per year.

	Arsenic	Cadmium	Chromium	Copper	Lead	Nickel	Zinc	Nitrate	Ammonium
2004	39	16	44	236	289	92	1552	117	142
2005	45	11	49	271	333	96	1575	119	141

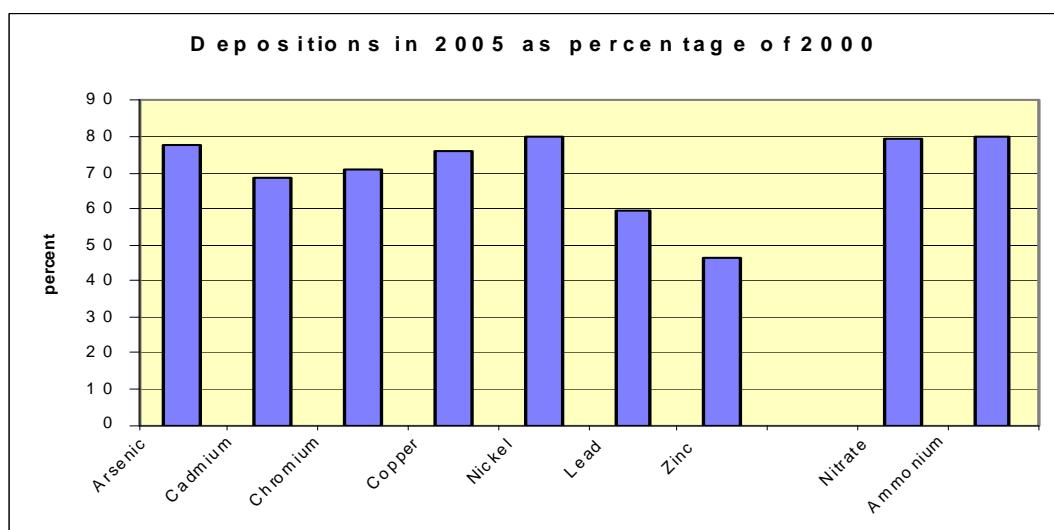

Figure 4.1: Estimated deposition change in 2000-2004, derived from measurements ('Method 3a')

* 'Method 3a' combines dry and wet deposition for metals. For nitrogen, wet deposition alone is used.

4.2 Temporal patterns in mercury depositions in 2001 – 2005

In order to begin to raise discussion for the construction of the upcoming 2009 CAMP data assessment, INPUT 2007 requested that the temporal patterns in mercury deposition be displayed in this report, and comment passed on the suitability of available data for such evaluation of temporal patterns. In Figure 4.2 the overall observed depositions of mercury are shown. This represents the average picture across stations with reports each year during the period 2001 – 2005.

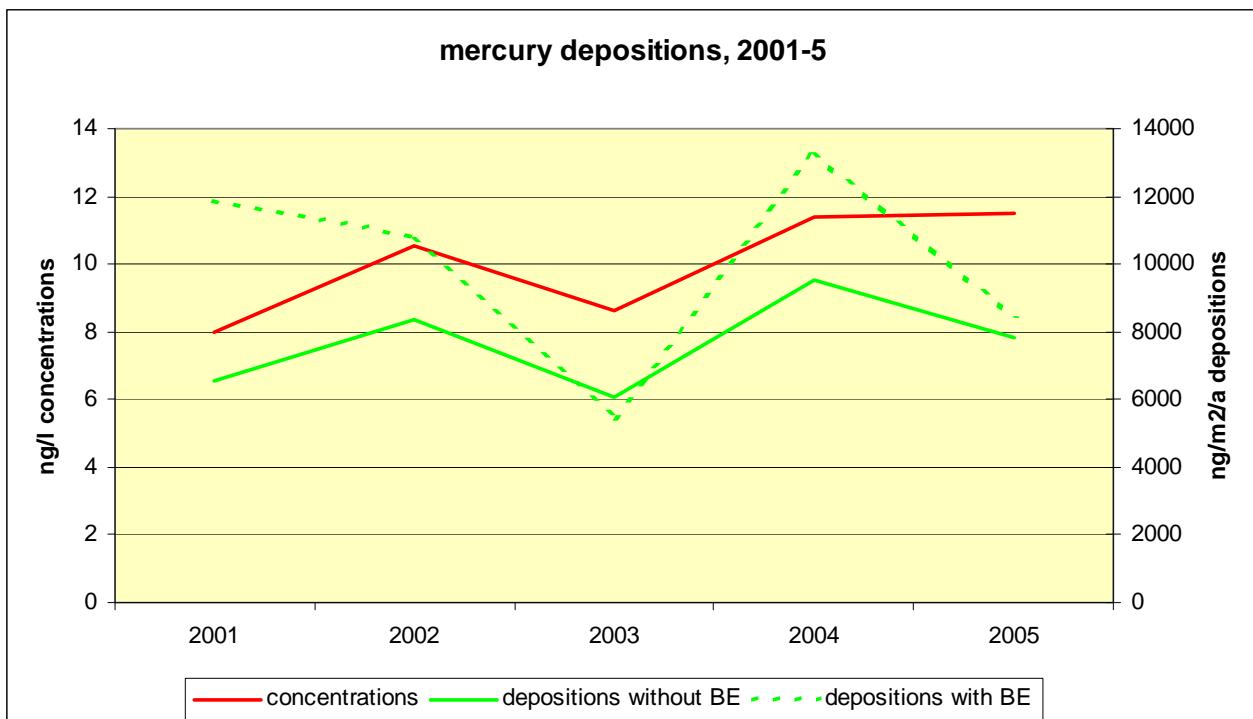

Figure 4.2: Average depositions of mercury on the North Sea coast, 2001 – 2005

The figure is constructed from observations in Germany, the Netherlands, Norway and Sweden. Continuous observations are also available from Belgium. However, in the Belgian data submitted to OSPAR there are notable variations, despite that Belgian performance in separate open intercomparison exercises has been similar to other countries. Inclusion of this data leads to large changes in average deposition across all sites from year to year. Part of this may be explained by less sensitive analysis of mercury in Belgium to 2005. Section 5.1 details detection limits. Average depositions with and without use of Belgian data is shown.

Even with the remaining data there are notable inter-annual changes. In Figure 4.2 there is suggestion of an increase in mercury depositions to the North Sea; for each of the individual stations this pattern appears still stronger. Construction of averaged summary pictures are very attractive from a communication point of view, but incur the cost of losing local detail. The use of CAMP data for construction of such overviews needs careful consideration during development of the CAMP Assessment Report.

4.3 Seasonality in nitrogen deposition

Nitrogen has been selected here for displaying temporal trends. To provide information at the regional scale observations have been averaged across all stations found in the North Sea (OSPAR Region II), and across all stations in all remaining regions, described broadly as the Atlantic.

Both nitrate and ammonium showed a spring peak in depositions in the North Sea, the peak being weaker for nitrate. For the Atlantic regions, the temporal pattern for ammonium concentrations was similar, albeit at lower absolute levels than seen in the North Sea. Nitrate showed a much less marked seasonal pattern. The lower peak/weaker seasonal pattern for nitrate nitrogen likely reflects a typically greater distance of transport between points of emission and deposition at the coast than is the case for ammonium. Sources are frequently from industry and transport, and are widely spread. The shorter typical distance of transport for

ammonium with consequent lesser dispersion will produce a clearer gradient in depositions away from emission sources. Ammonium sources are mostly agricultural and are often in proximity to the coast.

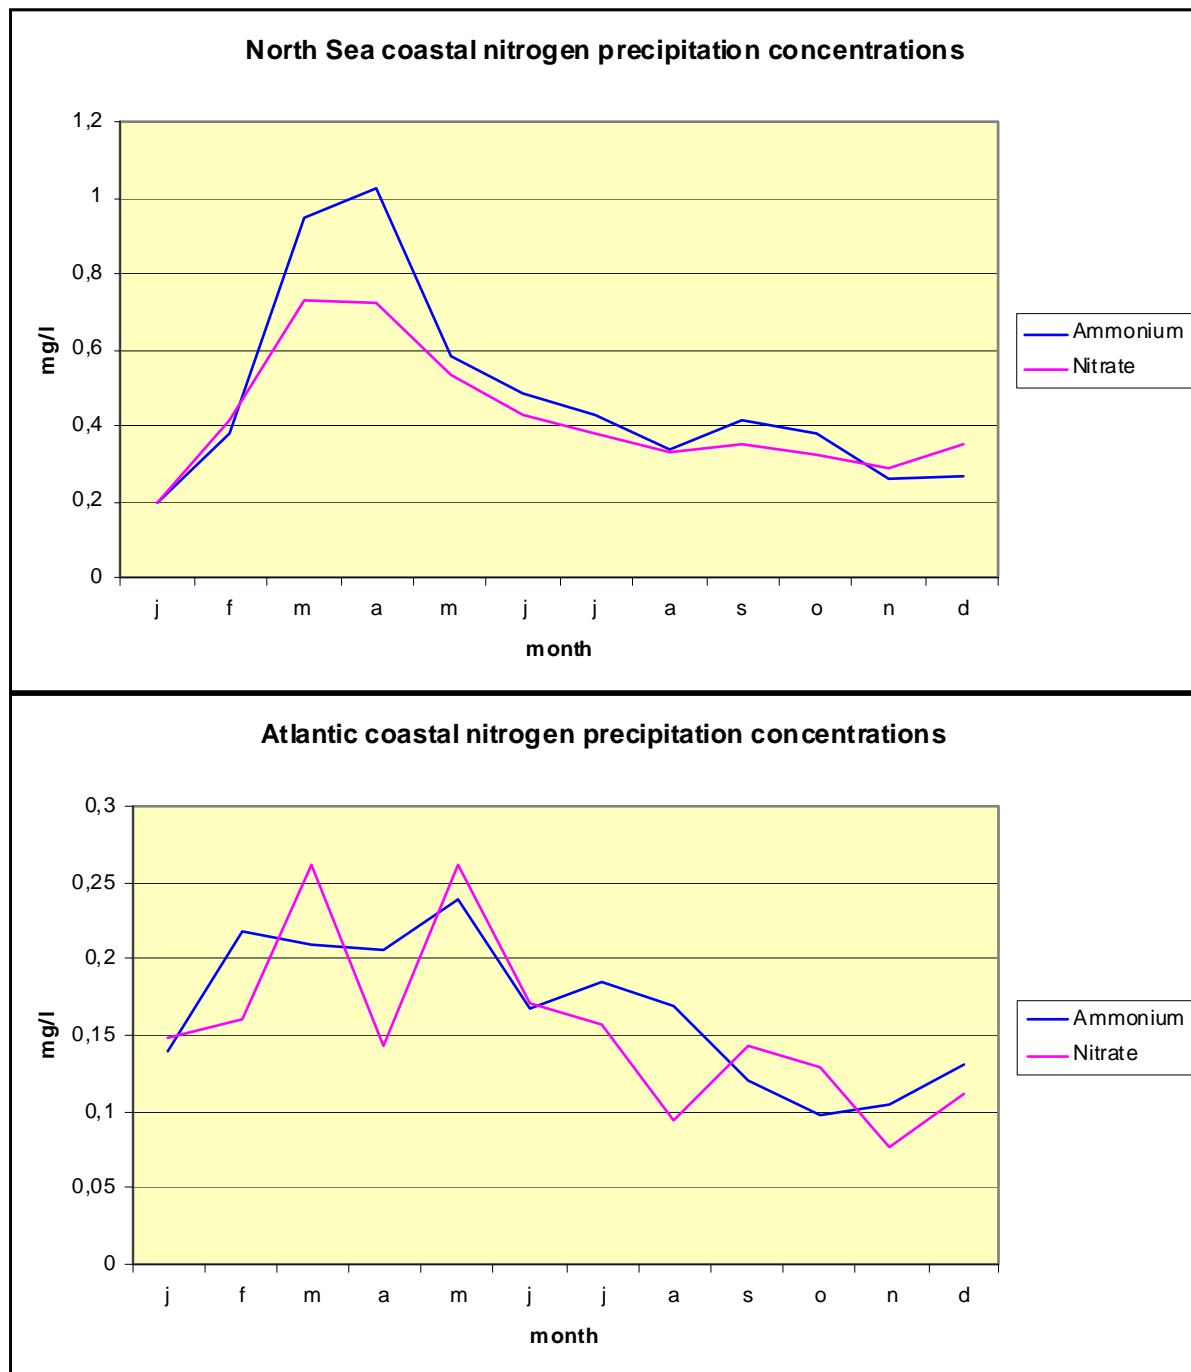

Figure 4.3: Seasonal pattern in precipitation nitrogen to the North Sea and NE Atlantic coasts in 2005

5. Data uncertainty

5.1 Limits of detection

INPUT 2006 has requested NILU to include the reported limits of detection or limits of quantification in the CAMP 2005 data report to INPUT 2007, and to provide an overview table of ranges of reported LoDs/LoQs per component and Contracting Party. At present, such information is not uniformly received under the CAMP. To encourage the process and discussion within Contracting Parties prior to the data call for the CAMP 2006 data report, a first overview of the current state of play is provided here.

Table 5.1: Reported detection limits; components in precipitation, and as sum precipitation + dry deposition.

The reported detection limits for components in precipitation are given in Table 5.1, whilst the equivalent for airborne compounds is found in Table 5.2. The methodology by which these are derived is largely unknown. The UK has submitted its approach. For components in precipitation a multiple of the standard deviation of averaged blanks is used. For metals, nitrogen and PCB in air the same approach is taken, whilst for remaining organics a multiple of the integral of baseline noise calibrated against standards is used. For other countries the approach is unknown. On occasions limits of quantification rather than limits of detection are used. Limits of quantification have no fixed means of estimation, and hence it is likely that dissimilar criteria will be applied between countries. Examination of the values nevertheless indicates some very large differences, sometimes of up to a factor of 1000 between most and least sensitive. Such differences reflect on the method and performance of sampling and analysis.

6. Final observations

Reporting of CAMP data for 2005 was reasonably good. Only one Party was unable to deliver data within the timetable. Difficulties in data handling at the European Environment Agency caused delays to delivery by one Party which were beyond the control of that Party.

Quality control of the data delivery process could still be improved. Amongst the problems with real time implications this year were: data reported for overlapping time periods, uncorrected station codes, data delivered as Excel sheets, data delivered in separate batches, varying units of measurement per component.

As in previous years, some countries provided extensive reporting of components not required by CAMP as mandatory or voluntary component. Some countries reported more non-CAMP than CAMP components. This data is stored and handled as for CAMP components, and thus represents a data handling workload beyond the CAMP. Whilst OSPAR can be imagined to have a broad interest in many of these extra contaminants, for some this is harder to imagine and it would appear that Parties will label all data from all programmes as suitable for CAMP, whether or not there is an imaginable interest. This would be a short-cut by countries but which significantly increases data handling.

A translation of the observations made by Contracting Parties into estimated depositions has been made for this report using the Method 3a. These estimates show marginal change since 2004, but notable decreases in depositions of most mandatory contaminants since 2000. Evaluation of temporal changes in mercury depositions, however, suggest no decrease. Indeed, the limited data available actually revealed rising depositions, although the reasons for this were not investigated. As was done for mercury and nitrogen in this report, the aggregation of observation data across several stations into a single figure for a sub-region is an approach which is common when providing summary information. OSPAR may wish to consider its suitability or its limitations with respect to the upcoming 2009 CAMP Assessment report.

Data quality is an issue which INPUT has previously begun to evaluate through the request for Parties to supply annual detection limit information as of 2005. Eight of the Contracting Parties have delivered at least partial data. There is variation in the approach to this question. Some countries utilise the concept of a limit of quantification, others use a limit of detection. Normal practice amongst chemists varies between components – for some pollutants the limit of quantification will be taken as a multiple of the limit of detection (i.e. is a stricter standard); for other components normal practice is to take limits of quantification and of detection as equivalent. The means of calculating each of these is unknown, but is quite possibly dissimilar. OSPAR may wish to consider more precisely what information it wishes countries to supply, and to consider this in light of how it wishes to see the information used. It is to be noted that, through data flagging, countries have always submitted information as to whether observed pollutant levels are below limits of detection.

<i>Percentage completion of voluntary programme</i>													49,43	49,4	

Components marked 'insufficient data' indicate insufficient data received for calculation of monthly means.

The requirement in the CAMP Principles is 50% coverage for calculation of monthly mean air concentrations.

(a) 7 days campaign, unknown date. Not submitted as NASA Ames format

(b) 11 days campaign, July. Not submitted as NASA Ames format

(c) 7 days campaign, October; 6 days campaign December. Not submitted as NASA Ames format

TITLE Pollutant deposits and air quality around the North Sea and the North-East Atlantic in 2005		PROJECT LEADER Kevin Barrett	
		NILU PROJECT NO. O-97146	
AUTHOR(S) Kevin Barrett		CLASSIFICATION * B	CONTRACT REF. Alan Simcock, Chairman
REPORT PREPARED FOR OSPAR Commission New Court, 48 Carey Street, London WC2A 2J!, United Kingdom			
ABSTRACT Report of the observations of airborne pollutants around the OSPAR coastlines, 2005. Displays the estimated deposition of nutrient, heavy metal and organic pollutants around the coast, together with estimates of the total load to the North Sea of pollutants from the atmosphere. There is indication of decline in pollutant loads.			
NORWEGIAN TITLE Pollutant deposits and air quality around the North Sea and the North East Atlantic in 2005			
KEYWORDS Marine atmospheric pollution			
ABSTRACT			

* Classification A Unclassified (can be ordered from NILU)

 B Restricted distribution
