Comprehensive Atmospheric Monitoring Programme

Observations from coastal stations in 1999

The Convention for the Protection of the Marine Environment of the North-East Atlantic (the "OSPAR Convention") was opened for signature at the Ministerial Meeting of the former Oslo and Paris Commissions in Paris on 22 September 1992. The Convention entered into force on 25 March 1998. It has been ratified by Belgium, Denmark, Finland, France, Germany, Iceland, Ireland, Luxembourg, Netherlands, Norway, Portugal, Sweden, Switzerland and the United Kingdom and approved by the European Community and Spain.

La Convention pour la protection du milieu marin de l'Atlantique du Nord-Est, dite Convention OSPAR, a été ouverte à la signature à la réunion ministérielle des anciennes Commissions d'Oslo et de Paris, à Paris le 22 septembre 1992. La Convention est entrée en vigueur le 25 mars 1998. La Convention a été ratifiée par l'Allemagne, la Belgique, le Danemark, la Finlande, la France, l'Irlande, l'Islande, le Luxembourg, la Norvège, les Pays-Bas, le Portugal, le Royaume-Uni de Grande Bretagne et d'Irlande du Nord, la Suède et la Suisse et approuvée par l'Espagne et la Communauté européenne.

Observations from Coastal Stations in 1999

Kevin Barrett

Norwegian Institute for Air Research
P.O. Box 100, N-2027 Kjeller, Norway

Preface

This report was presented as a draft at the INPUT meeting in London 30 January–1 February 2001. Corrections received from the Parties between January and May 2001 were taken into account during the preparation of this corrected report.

This final version was delivered to the OSPAR secretariat in June 2001. A full list of national data originators can be found in Appendix D. At NILU the following have been responsible for CAMP data management: Jan Schaug, Anne-Gunn Hjellbrekke, Torunn Berg, Rita Larsen, Terje Krognes, and Kevin Barrett.

Observations from Coastal Stations in 1999

1 Introduction

This report describes the observations reported by coastal monitoring stations across the OSPAR region (see Figure 1.1) under the Comprehensive Atmospheric Monitoring Programme (CAMP) for the year 1999. It was presented to the Working Group on Inputs to the Marine Environment, OSPAR, London, 30 January – 1 February, 2001, and is now released after this review.

The monitoring regime proposed by CAMP is summarised in chapter two. This section lists the components for which monitoring is suggested, the methods of sampling, and the recommended location of monitoring sites. In support of this summary, the Principles for the CAMP as described in the Summary Record for the Environmental Assessment and Monitoring Committee (ASMO) of OSPAR annual meeting at Spa, 1998, is given in Appendix B. For reference, a description of the NASA/Ames format in which form the reporting of data is requested is provided in Appendix C.

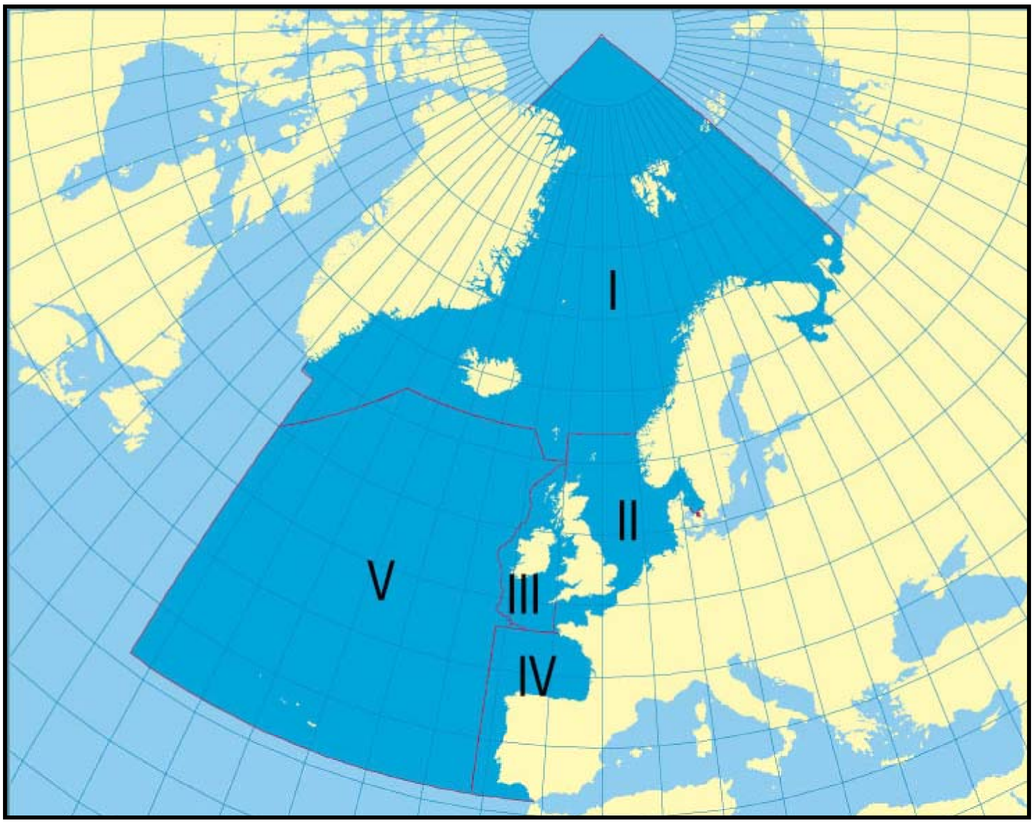

Figure 1.1: OSPAR maritime area and regions:
1: Arctic waters 2: Greater North Sea 3: Celtic Seas 4: Bay of Biscay and Iberian Coast 5: Wider Atlantic. Source: www.ospar.org.

Chapter three summarises the monitoring activities which served CAMP in 1999, listing the stations reporting, their individual monitoring regimes, and the components they have reported. This is intended as an overview of the achievement of the implementation of CAMP recommendations. Actual observations are summarised as annual mean values in chapter four. The monthly values themselves from each station for 1999 are provided in Appendix A either as reported, or after aggregation to monthly values from shorter periods. Finally, Appendix D supplies a list of the current contact names and addresses for the data originators in each country, and for the CAMP Data Manager.

2 The Comprehensive Atmospheric Monitoring Programme

The Comprehensive Atmospheric Monitoring Programme forms one element within the wider Joint Assessment and Monitoring Programme of OSPAR. Amongst the intentions of CAMP are assessment of the atmospheric input of selected contaminants to the OSPAR maritime area and regions (see Figure 1.1). This is to be achieved via a monitoring regime with indicated substances, time resolution, methodologies, and sampling locations. Thus defined, the programme may assist in assessment of the quality status of the marine environment.

The components of interest to CAMP are divided into two groups, for measurement on a mandatory basis and for measurement on a voluntary basis. These are listed in table 2.1.

2.1 Components

Table 2.1: Components to be measured within CAMP.

	Mandatory	**Voluntary**
Precipitation	As, Cd, Cr, Cu, Pb, Hg, Ni, Zn, γ-HCH, NH_4^+, NO_3^-	PCB 28,52,101,118,138,153,180 Phenanthrene, anthracene, flouranthene, pyrene, benzo(*a*)anthracene, chrysene, benzo(*a*)pyrene, benzo(*ghi*)perylene, indeno(*1,2,3-cd*)pyrene
Airborne	NO_2, HNO_3, NH_3, NH_4^{+a}, NO_3^{-a}	As, Cd, Cr, Cu, Pb, Hg, Ni, Zn, γ-HCH, PCB 28,52,101,118,138,153,180, Phenanthrene, anthracene, flouranthene, pyrene, benzo(*a*)anthracene, chrysene, benzo(*a*)pyrene, benzo(*ghi*)perylene, indeno(*1,2,3-cd*)pyrene, NO

[a]) total ammonium (NH_3 + NH_4^+) and total nitrate (HNO_3 +NO_3^-) is an alternative.

For quality assurance purposes the reporting of pH, electrical conductivity, and concentrations in precipitation of all major ions (Na^+, K^+, Mg^{2+}, Ca^{2+}, SO_4^{2-}, Cl^-, NH_4^+, NO_3^-, HCO_3^-) is also encouraged.

2.2 Sampling

Precipitation sampling using wet-only samplers is recommended. Regular inter-comparisons between wet-only and bulk samplers should be undertaken where bulk samplers are used instead. Account should be taken of any need to undertake summer cooling of samples.

For measuring precipitation amount practice has shown variable results in the efficiency of chemical samplers. According to design, problems such as poor capture, evaporation or snow blow-out can influence results. The use of a standard rain-gauge parallel to the chemical sampling can assist in the calculation of deposition fluxes from concentrations and precipitation amounts.

Currently acceptable precipitation sampling frequencies are between one week and one month. The recommendation, however, is for one week sampling, possibly with combination of samples to longer periods (e.g. one month) prior to analysis. It is recommended to have two sampling periods for weeks which cross month boundaries, even if one of these is only a one-day sample. Achieving equal months in reported values greatly aids comparability between samples taken in different countries. Where weekly samples are simply assigned to the month in which most days fall noticeable temporal errors in data may, of course, be introduced. This is even more true where two-week samples are taken. The recommendation to change samples on the first day of the month in addition to the periodic routine is most strongly endorsed by NILU as CAMP Data Manager for all sample periods, and most especially when longer/two week sampling periods are used. As an aid to achieving consistency, it is recommended that samples are always changed at a fixed time, e.g. at 08.00 UTC on each Tuesday and on the first day of each month.

Amongst airborne components, a sampling period of 24 hr is recommended for heavy metals and for POP's, not less than 24 hr for nitrate and ammonia, with continuous monitoring of NO and NO_2 aggregated to hourly values.

2.3 Station siting

The Principles for CAMP call for each Contracting Party bordering the maritime area (excluding EU) to operate at least one monitoring station as part of CAMP. Where Parties border more than one region (see Figure 1.1) at least one station should be operating in each. These stations should be so-called *background stations*, i.e. not directly influenced by emission sources local to them. The intention of the programme is assessment of inputs to the marine environment. In accordance with this, the Principles explicitly call for stations to be located not more than 10 km from the coastline.

2.4 Data reporting

The monitoring data assembled through CAMP is stored on a relational database. This must account for considerable diversity in procedures across countries. In some cases several separate instruments operate side-by-side to serve different programmes. In others data is aggregated from the same instrument in different ways before submission to different programmes. On occasions different components are reported to different programmes from the same instrument. More than one person in some countries may have responsibilities in reporting data to programmes. Correct association of observed concentrations with observed precipitation amounts is vital. The potential for data duplication or mis-attribution is significant.

In consequence, all data reported to CAMP should be very carefully identified. As well as station and component identification, all data originators in participating countries are asked to assign unique names to the field instruments, to the methodologies, and to ensure programme labelling. Reporting is also requested in a standardised format which seeks to ensure comparability and allow quality assurance. The NASA/Ames format of reporting is used for data files, being thus-named after development by NASA. A description of the format is given in Appendix C.

Flagging of data is an important aid to quality management in use of the data. Data originators may be aware of unusual uncertainties associated with individual data elements. It is also important to be able to indicate such factors as concentrations being found to be below the analytical detection limit. Also in Appendix C is a list of the flags which may be used to mark any data element.

The time schedule for data reporting calls for initial submission of data by countries to the CAMP Data Manager by 31 August in the year subsequent to monitoring. Following initial reporting-back by the Data Manager in draft form, participants are requested to submit revised or corrected data by 30 October.

The CAMP principles call for monitoring stations to be located where possible within ten kilometres of the coast. By-and-large this objective is met, although observations from a few more distant sites have been reported for 1999.

In addition to that indicated in Table 3.2, national data originators have indicated that monitoring of nitrogen has been conducted by the United Kingdom, and monitoring of γ-HCH has been undertaken by Germany. These results are to be supplied to CAMP in the future as soon as national processing is completed.

Spain											
Sweden	•	•	•		•	•	•	•		•	•
United Kingdom	•	•	•	•	•		•	•		•	•

In general a number of countries found the reporting deadlines rather tight. Whilst some 1999 data was received at the database in the summer of 2000, the latest dataset received which is included in this report arrived on January 4th, 2001. No data was available from Spain before reporting, and data was still anticipated from a number of countries.

Ireland	$\bullet^{7}$										pesticides
Netherlands											
Norway											
Portugal											
Spain											
Sweden											
United Kingdom											

Number in superscript for PCB indicates number of individual congeners reported.

The recommended CAMP voluntary monitoring programme for components in precipitation has not been closely adhered to. It should be mentioned that monitoring of a number of these components has been undertaken by Germany, and that these results are anticipated to be released to CAMP in the near future.

Letters in parenthesis: Reporting frequency

The sampling regimes across the stations do not always permit ready estimates of equivalent monthly observations. Notable is the procedure in the Netherlands with four-week sampling irrespective of calendar months, and the single two month sample at one UK site on one occasion. This produces 13 sampling periods per year with a somewhat uncertain attribution within calendar months. Several countries do not recommence their chosen monitoring period at the start of each month as recommended. A similar issue of comparability arises with the temporal resolution of reported data. Whilst some countries collect samples during a month and combine these prior to analysis, others analyse samples at a finer resolution. These may then be reported directly in 'raw' state, or may be aggregated by the host country to monthly values for reporting. There is potential for inconsistent treatment of data in consequence, notably with respect to flagged data.

4 Observed Atmospheric Quality

In this chapter the annual average values of the mandatory and the voluntary list substances are provided as an overview of atmospheric conditions around the North East Atlantic in 1999. Observations of nitrogen and of arsenic, cadmium, copper and lead are plotted to provide a view of spatial distributions. The reported data in monthly format is provided in Appendix A.

In making the annual estimates all samples flagged 659, 658, 654, 653, 599, 499, 460, 459, 458, 260, 259, or 256 were excluded (see Appendix C for list of data flags). **NOTE**: The CAMP principles have been followed with respect to detection limits. Where flag 780 was given, this data value was employed. Where 781 was flagged, a value of half the detection limit was used.

4.1 Nitrogen

In Figures 4.1 and 4.2 the estimated depositions of nitrogen in precipitation across the CAMP region are shown. Values represent the sum of precipitation-weighted monthly mean concentrations multiplied by precipitation amount for those CAMP stations reporting nitrogen in precipitation. The summed annual values can be found in Table 4.1. Some of the tabulated data was not employed where this was apparently elevated in comparison to neighbouring stations or previous years. Preliminary evaluation of data at NILU led to withdrawal and resubmission of revisions through to January 2001. This new data is included here. Associated air concentration data is presented in Table 4.2 (mean annual values).

Table 4.1: Mean precipitation weighted concentrations of reduced and oxidised nitrogen in precipitation(mg N l^{-1}), plus estimated annual wet depositions (mg N m^{-2}). Year: 1999.

4.2 Metals

Tables 4.3 and 4.4 lists the annual summary data for metal deposition in precipitation around N.E. Atlantic coasts. The spatial patterns are illustrated for arsenic, cadmium, copper and lead in Figures 4.3-4.6. Table 4.5 provides annual average concentrations in air.

Included in the precipitation tables for BE0004 are estimates on the basis of two samples collected simultaneously at the station using both bulk and wet-only sampling devices. The CAMP principles propose side-by-side comparisons where bulk samplers are used. However, comparison in this case is complicated through different laboratories and different methodologies being used for analysis of samples from each sampler. Samples from the bulk collector are analysed at a laboratory in Antwerp using AAS, whilst samples from the wet-only collector are analysed using Graphite furnace AAS at a laboratory in Ghent which commonly undertakes water quality analysis. Example estimates from these two monitoring and analytical regimes are given in Table 4.6. The difference in estimates can amount to a factor of ten. Monthly values for each of these can be found in Appendix A. Metal measurements are generally difficult due to the low concentrations and the contamination problem. A bulk sampler will collect dry as well as wet deposition, and the sample will be concentrated due to water evaporation during the warm season. In this case, however, the bulk results are the lowest and should be given most confidence. Although sampling method intercomparison is hampered by differences in analysis method, this case provides a good example of the value to be gained from precise labelling of field instruments, and informative reference labelling of laboratory methods. Different data sets such as these can thus be identified in the database. Following review at INPUT 2001, Belgium has decided to undertake CAMP analysis at the Antwerp laboratory in future.

The mercury concentrations in precipitation at BE00021 are too low compared with other measurements, and there is in general a need to review this data. The high concentrations of cupper at IS0090 may be due to local influence.

Metal data frequently are below the detection limits of analytical devices. When all or nearly all results are below the detection limit, the averages and depositions in Table 4.3 and 4.4 have been given as upper limits only. This calculation may not be completely consistent in this report, and there is a need to work out better calculation procedures, preferably in co-operation with HELCOM and EMEP.

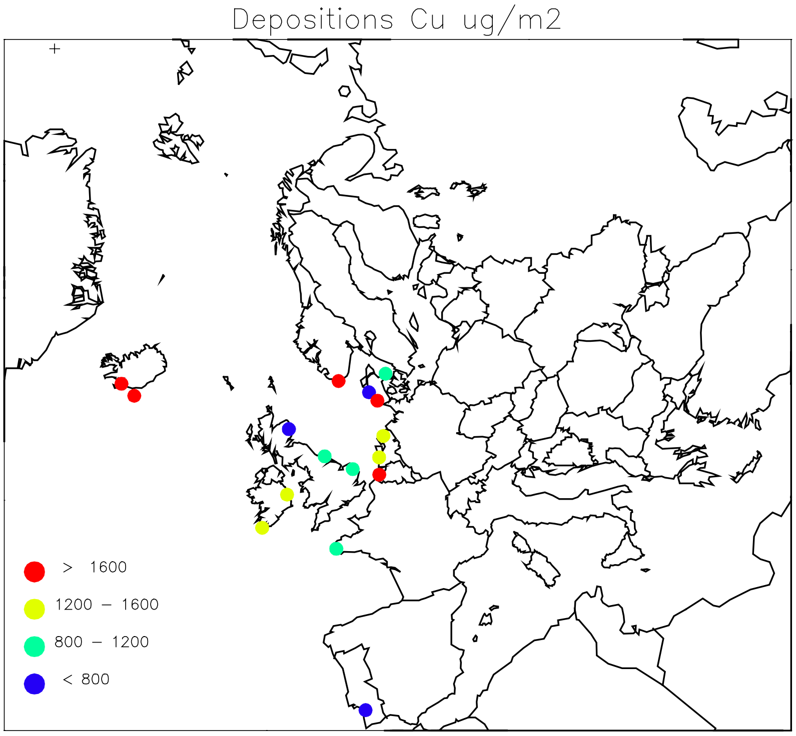

Figure 4.3: Estimated deposition of copper in precipitation, 1999. Units: µg Cu m^{-2}yr^{-1}.

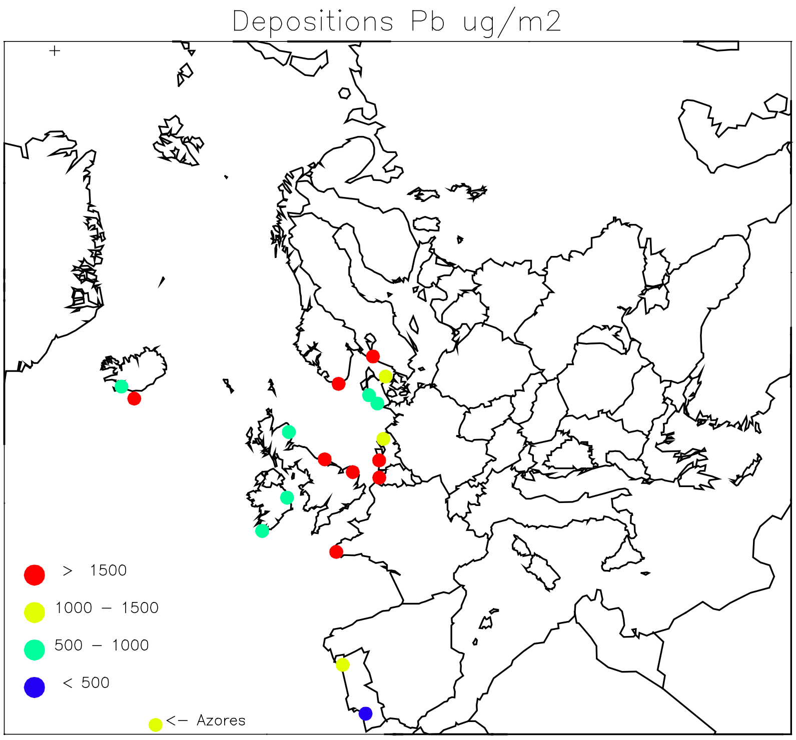

Figure 4.4: Estimated deposition of lead in precipitation, 1999. Units: µg Pb m^{-2}yr^{-1}.

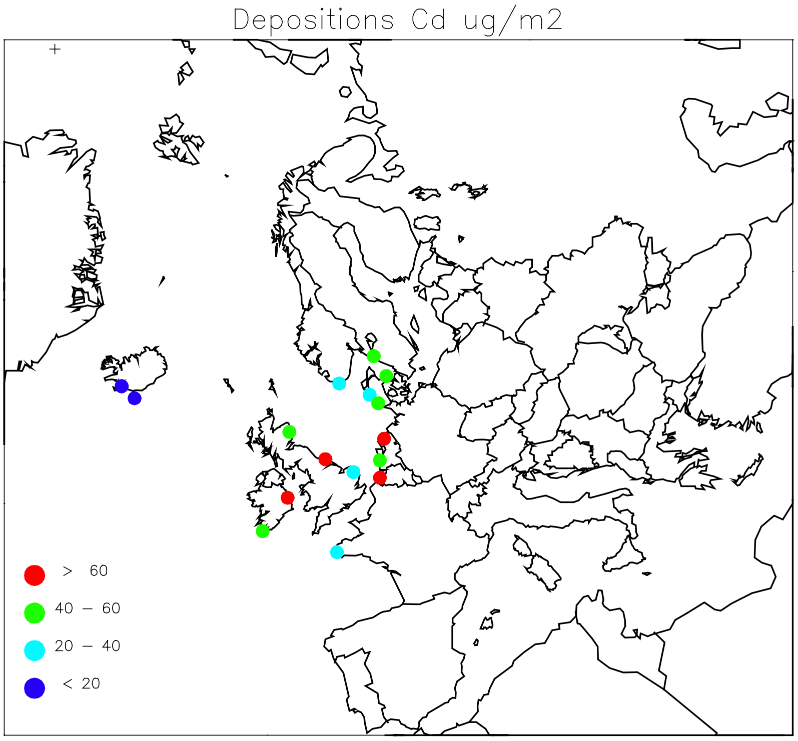

Figure 4.5: Estimated deposition of cadmium in precipitation, 1999. Units: µg Cd $m^{-2}yr^{-1}$.

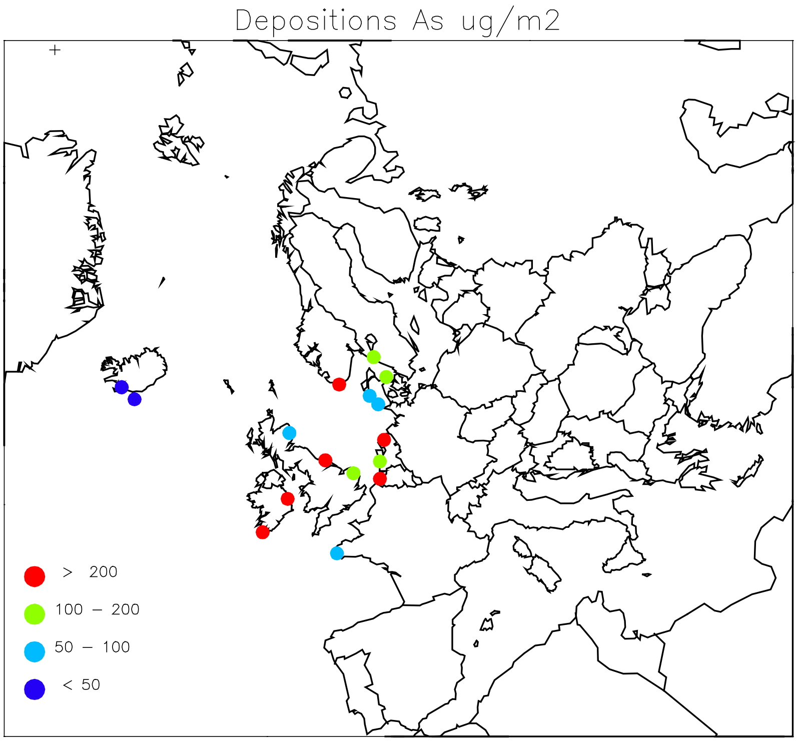

Figure 4.6: Estimated deposition of arsenic in precipitation, 1999. Units: µg As $m^{-2}yr^{-1}$.

4.3 Organic compounds

Finally, in Tables 4.7–4.12 the annual average values for organic compounds reported to CAMP are listed. More results are anticipated in the near future from different countries. With restricted data it is more difficult to identify factors of relevance in interpreting data and developing monitoring efforts. Nevertheless quite strong differences in reported concentrations of some organic compounds between sites suggests either marked gradients, or differences in techniques which may be beneficial to evaluate. Concentrations of organic compounds like of metals frequently are below the detection limits. Comments given with respect to the treatment of metal data are also valid for the organics.

5 Summary

This report contains the results of monitoring undertaken for CAMP during 1999. The programme calls for Mandatory Monitoring of a range of nutrients, heavy metals and organic compounds in precipitation and air, and encourages participation in a Voluntary Monitoring of additional compounds. Monitoring should be conducted at monitoring stations located in proximity to the coast. Most stations do meet the ten kilometre objective. The furthest station from the coast is located some 26 kilometres inland.

Participation in the Mandatory programme for components in precipitation is reasonable. Some environmental toxins, e.g. γ-HCH and mercury receive less attention than other compounds. Monitoring of airborne compounds is at a similar level of compliance. Rather less attention is given to the Voluntary programme, notably the precipitation element in which organic substances feature. Some data is anticipated in the near future after national processing, but will still mean that observations are only reported from a single site.

Whilst equivalence in monitoring periods between countries is reasonable, there are some clear exceptions. A number of countries do recommence their monitoring periods at the start of each month thus allowing true monthly values to be reported or derived. However, a number do not do this, and some have long monitoring periods straddling months. This can make comparability less straightforward.

Reporting practices also vary between countries. Whilst some aggregate all samples in each month prior to analysis, others aggregate the results of several shorter samples, whilst others report raw short-period data. There is a reasonable prospect that data handling will be different as a consequence of this.

Metal and organic concentrations frequently are below the detection limits of analytical devices and in some cases detection limits are unusually high; this calls for strict rules when aggregating such data. Procedures may be worked out in co-operation with HELCOM and EMEP.

Differences in techniques and laboratories may be worth some evaluation. Example review of side-by-side samples analysed at different laboratories yielded tenfold differences in estimates. Similarly, there are quite clear differences in the estimates provided by different countries which may not only reflect differences in environmental occurrence.

Appendix A

Observed monthly mean concentrations in precipitation and in air at CAMP coastal monitoring stations, 1999

Appendix is divided by country, and thereafter by station. Each station heading contains observations of both precipitation and airborne concentrations during 1999. The following countries and stations which reported data for 1999 are listed.

Appendix B

Principles for the Comprehensive Atmospheric Monitoring Programme (CAMP)

1. Objectives

The main objectives of the CAMP are to monitor the concentrations of selected contaminants in precipitation and air and their depositions in order:

- to assess, as accurately as appropriate, the atmospheric input of the selected contaminants to the maritime area and regions thereof on an annual basis;
- to determine long-term trends in atmospheric inputs;
- for their use in relation to modelling activities, specifically to validate atmospheric transport models used for assessments of atmospheric inputs to maritime area.

2. The network[1]

Each Contracting Party bordering the maritime area (EU excluded) should have at least one monitoring station on the coast and/or offshore to be included in the joint monitoring programme. Contracting Parties which border more than one OSPAR Region should have at least one monitoring station at the coast and/or offshore within each. The station should be a so-called *background station*, that is, a station which is not directly influenced by local sources. The station should be located not more than 10 km from the coastline. At the station simultaneous measurements of the chemical composition of air and precipitation are to be performed.

3. Chemical composition of precipitation

3.1. Components to be measured[2]

The following contaminants are to be measured on a mandatory basis in precipitation:

• heavy metals:	arsenic cadmium chromium copper lead mercury nickel zinc
• persistent organic contaminants:	γ-HCH[3] (lindane)
• nutrients:	ammonium (NH_4^+) nitrate (NO_3^-)

[1] Contracting Parties should take into account developments within the framework of other international organisations (particularly AMAP, EMEP, HELCOM and WMO).

[2] Not all contaminants included in the Joint Assessment and Monitoring Programme (JAMP) are mentioned here as mandatory or voluntary components. Reasons are either because the atmospheric pathways are negligible (e.g. oil, TBT) or because routine monitoring methods are extremely expensive or not yet fully developed (e.g. furans, dioxins). However, when information is available, for example during a measuring campaign, Contracting Parties are strongly encouraged to submit these data to the data base manager.

[3] In view of the low concentrations, the monitoring of α-HCH is no longer mandatory. When γ-HCH is not measured as a separate component, it should be clearly stated in the data reports that total HCH has been measured.

The following contaminants should be measured on a voluntary basis in precipitation:

- persistent organic contaminants: the PCB-congeners 28, 52, 101, 118, 138, 153 and 180[4]
  the following PAHs: phenanthrene, anthracene, fluoranthene, pyrene, benzo[*a*]anthracene, chrysene, benzo[*a*]pyrene, benzo[*ghi*]perylene, indeno[*1,2,3-cd*]pyrene

For quality assurance purposes Contracting Parties are encouraged to report pH, electrical conductivity and the concentrations in precipitation of the major ions (Na^+, K^+, Ca^{2+}, Mg^{2+}, SO_4^{2-}, Cl^-, NH_4^+, NO_3^-, HCO_3^-).

3.2. Sampling and analysing methods[5]

For CAMP the use of wet-only samplers is recommended. The use of bulk collectors is acceptable when on a regular basis, an intercomparison of results of wet-only and bulk samplers actually in use in the network takes place. Samplers should be designed for sampling during all seasons and climatic conditions. Formation of ice in funnel or bottle must be avoided; at stations where high temperatures are expected in the summer, cooling of the samples might be needed. The size of funnel and bottles should be adapted to the length of the sampling period and expected precipitation amount.

Each individual sampler must be identified with a short, unique name[6], for bulk precipitation samplers, the bucket stand is named and the bucket itself is a nameless consumable. All measurements must be related to a field sampler or instrument identified in this manner. Official precipitation amounts should be reported where available (see paragraph 3.4). In addition, the precipitation amount measured in each individual sampler must be reported.

There are several methods for analysing of heavy metals (excluding mercury) in precipitation and in aerosol filters. Direct methods without extraction of the filters are instrumental neutron activation analysis (INAA), particle induced X-ray emission (PIXE) and X-ray fluorescence. Methods for analysing heavy metals in precipitation and dissolved particles from filters are atomic absorption spectroscopy (AAS) with flame- or electrothermal atomisation, inductively coupled plasma optical emission spectroscopy (ICP-OES) and inductively coupled plasma mass spectroscopy (ICP-MS). The latter method (ICP-MS) has been recommended at an EMEP workshop (Moscow, September 1996) as the analytical reference method for the heavy metals As, Cd, Cr, Cu, Ni, Pb, and Zn.

---

4 Although atmospheric input is estimated to be the most important input route to the maritime system it is judged not appropriate to recommend the mandatory monitoring of PCBs taking into account that PCBs were due to be phased out in all Contracting Parties. In this regard it is proposed that it is more appropriate to recommend targeted monitoring activities in areas expected to have relatively high PCB loads.

5 See for an overview of sampling and analysing methods currently in use within Europe the report and proceedings of the workshop on the assessment of EMEP activities concerning Heavy Metals and Persistent Organic Pollutants and their further development, Moscow, Russian Federation, 24-26 September 1996; Report 117, Volumes I and II, World Meteorological Organisation, Global Atmospheric Watch, Geneva, Switzerland.

6 For more details, see chapter 6.1.

In designing a sampling methodology the JAMP guidelines for the Sampling and Analysis of Mercury in Air and Precipitation and the JAMP Guidance Note on Sampling and Analysis of PCBs in Air and Precipitation should be taken into account[7].

In general terms the detection limits of the measured contaminants should be well below the ambient levels by a factor of 10.

3.3. Sampling frequency

Sampling periods from one week to one month are acceptable. It is recommended however, that samples should be taken on a weekly basis in order to reduce the risk of (bio)chemical change in samples and/or the accidental contamination of samples (e.g. via bird droppings). When the samples are stored in a safe way (e.g. frozen) two or more samples can be combined before analysis to longer, regular intervals (e.g. monthly or 4-weekly averaged samples).

If weekly sampling is used and if a week includes two adjacent months, the measured data should be allocated to the month which comprises the largest number of days in the week in question. It is recommended , however, to have two sampling periods for a week that crosses a month boundary, even if one of these is only a one-day sample. It is recommended that samples are always changed at a fixed time (e.g. at 8.00 am (UT)) on every Tuesday and on the first of every month.

3.4. Precipitation amount

For the evaluation of the chemical composition of precipitation and for the estimation of wet deposition fluxes correct data on precipitation amounts is needed. Common practice has shown that the efficiency of chemical samplers for sampling of precipitation may differ considerably even for identical samplers; this results in different "observed" precipitation amounts (and therefore wet deposition fluxes). Parallel to the chemical measurements a standard rain gauge should be used according to WMO recommendations for measuring the precipitation amount. Alternatively, the results of a nearby located meteorological station which is shown to be representative for the CAMP-location may be used.

4. Chemical composition of ambient air and aerosol

4.1. Components to be measured

The following contaminants are to be measured on a mandatory basis in air:

- nutrients: in gaseous phase: NO_2, HNO_3, and NH_3
  in aerosol phase[8]: ammonium (NH_4^+) and nitrate (NO_3^-)

The following contaminants should be carried out on a voluntary basis in air:

- heavy metals: arsenic
  cadmium
  chromium
  copper
  lead
  mercury

---

7 Secretariat Note: these JAMP Guidelines are available from the OSPAR Secretariat on request.

8 As an alternative total nitrate (sum of gaseous HNO_3 and particulate NO_3) and total ammonium (sum of gaseous NH_3 and particulate NH_4) can be measured.

	nickel zinc
• nutrients:	NO
• persistent organic contaminants:	γ-HCH (lindane) the PCB-congeners 28, 52, 101, 118, 138, 153 and 180 the following PAHs: phenanthrene, anthracene, fluoranthene, pyrene, benzo[a]anthracene, chrysene, benzo[a]pyrene, benzo[ghi]perylene, indeno[1,2,3-cd]pyrene

4.2. Sampling and analysing methods[9]

High volume samplers or medium volume samplers equipped with cellulose fibre filters or membrane filters are currently in use for collection of aerosol. The recommended analytical method for As, Cd, Cr, Cu, Ni, Pb, and Zn is ICP-MS; other analytical methods are mentioned in section 3.2.

In designing a sampling methodology the JAMP Guidelines for Sampling and Analysis of Mercury in Air and Precipitation[10] and the JAMP Guidance Note on Sampling and Analysis of PCBs in Air and Precipitation[11] should be taken into account.

In general terms the detection limits of the measured contaminants should be well below the ambient levels by a factor of 10.

Knowledge of the particle size distribution is desirable for estimating dry deposition fluxes; size distribution forms an essential input parameter in transport/deposition models. Size distributions of heavy metal particles have been extensively studied with the help of cascade impactors. For routine monitoring cascade impactors are too expensive; a separation into two classes (cut-off at 2.5 μm) is possible using commercially available samplers.

4.3. Sampling frequency

For heavy metals and POP in gas and aerosol phase a sampling period of 24h is recommended. When only a limited number of samples can be taken within a given time period (e.g. due to budgetary constraints) it is suggested to take one 24h sample every five or six days[12]. In this strategy the number of samples to be analysed is limited to 70 or 60 annually; in this way, seasonal changes might be detectable and a reliable yearly averaged concentration will be obtained. In monitoring pesticides a higher frequency during the application period might be necessary.

---

9 See for an overview of sampling and analysing methods currently in use within Europe the report and proceedings of the workshop on the assessment of EMEP activities concerning Heavy Metals and Persistent Organic Pollutants and their further development, Moscow, Russian Federation, 24-26 September 1996; Report 117, Volumes I and II, World Meteorological Organisation, Global Atmospheric Watch, Geneva, Switzerland.

10 Adopted by ASMO 1997; final version (23 February 1998) circulated to Contracting Parties on 24 February 1998.

11 Adopted by ASMO 1997; final version (23 February 1998) circulated to Contracting Parties on 24 February 1998.

12 A sampling frequency of once per week should be avoided as this might introduce a systematic error. There is, for example, a clear difference in NO_x concentrations during the weekend and during working days. For heavy metals and POP such systematic differences can not be excluded a priori.

With respect to the nitrogen species, the gaseous compounds NO and NO_2 should be measured on a continuous base (aggregated to hourly averages before reporting); for the other N-compounds sampling period/frequency should not be less than 24h-average samples on a daily base.

5. Quality assurance

The low ambient concentrations of trace elements will easily cause wrong measurements if strict precautions are not taken to prevent contamination and other sources of errors. Quality assurance (QA) is therefore recognised as an essential component in air quality monitoring. Until now a quality assurance and quality control programme for the CAMP network has not been developed. It is strongly recommended to develop such a programme in close co-operation with other international monitoring networks (in particular, HELCOM, AMAP and EMEP)[13]. It is unlikely that full QA procedures will be established in the short term in all laboratories participating in CAMP. Nevertheless a minimum requirement, to ensure that comparable quality data is produced, must be established. This minimum program should include the following points:

- requirements on documentation of procedures for sampling and analysis;
- a training programme for the persons involved in the various tasks of the monitoring procedure;
- regular of analytical intercalibrations of prepared samples;
- field intercalibrations of sampling and analyses;
- implementation of an audit program where stations are visited by experts.

It is essential that all participating organisations agree a programme to introduce QA procedures (at least the minimum set given above) and make a commitment to their strict adherence.

6. Reporting Procedures

In accordance with the OSPAR/NILU Data Management Contract, Annex 1, as presented to INPUT(1) 1998 (cf. INPUT(1) 98/3/Info.1)[14], Contracting Parties should submit, on a yearly base, CAMP data to the database manager (NILU, Kjeller, Norway) using a reporting format and according to the time schedule attached at Appendix 1. To allow data exchange and QA co-operation with EMEP, EMEP naming conventions should be used for organisation codes, station codes, field instrument references and sampling method references. In cases where the monitoring of components on the voluntary list is not performed, it would be useful if the Contracting Parties concerned could provide a short justification for not including these measurements in their national monitoring programmes.

Contracting Parties have to provide the database manager with one contact point (institutes and contact person) which is responsible for the monitoring activities on CAMP stations and which can serve as contact point for the exchange of information concerning

---

[13] See e.g. the conclusions and draft recommendations of the EMEP-WMO workshop on data analysis, validation and reporting, Usti nad Labem (Czech Republic), 27-30 April 1997, UN-ECE.EB.AIR/GE.1/1997/7.
One recommendation of the workshop may need special attention: results from various field intercomparisons of heavy metal deposition showed large differences between deposition even from identical samplers close to each other. A strong reduction in uncertainties can be realised by parallel measurements with at least two identical samplers at one site. When two or more samplers are installed, procedures for detecting outliers and for reporting the measurements (e.g. is the averaged or median value reported) have to be defined.

[14] Secretariat Note: details available from the OSPAR Secretariat on request.

monitoring data, atmospheric inputs of contaminants to the maritime area, methods of analysis of atmospheric contaminants and possible intercalibration activities.

6.1. Additional requirements on information of monitoring stations[15]

For a proper evaluation of the monitoring results the following (meta) information on the station should be supplied to the database manager:

- station name and station code;
- organisation responsible for operation of the station and name of contact person;
- co-ordinates; clearly indicate whether co-ordinates are given in degrees-minutes-seconds or in degrees and decimal units;
- altitude: height of the station above sea level (m);
- start date: date on which the station became operational;
- description of station environment: describe the siting of the station (e.g. located in a nature area, an agricultural area mainly with intensive cattle breeding);
- description of main emission sources: describe the nearest pollution sources (e.g. nearest city is Leyden (150,000 inhabitants, 15 km in southern direction);
- meteorological parameters measured at the station in addition to air contaminants;
- prevailing meteorological conditions (e.g. wind rose).

For each component the following information on the measurement configuration is needed:

- component;
- for automatic devices: name/type/version of monitor and measurement technique;
- for manual or semi-automatic devices: name/type of equipment to obtain sample, analytical principle used;
- calibration method, frequency of calibration;
- integration time of results;
- height of sampling point above surface;
- length of sampling line;
- whether the sampling line is heated;
- start/end date of configuration.

An organisation is defined as the operator of a station and the owner of a field instrument. The organisation code has the form NL01L (the last L declares that this organisation is a laboratory, and it is laboratory 1 in the Netherlands). Station number 3 in the Netherlands will have the code NL0003R (4 digit number, + the code R for regional background station). The organisation may have bulk samplers operated at several stations. We need to relate the sampler to the organisation with a reference like NL01L_bu1. A reference in this context is always constructed by the organisation code, an underscore character, and a name (the name only needs to be unique within the organisation that creates it, the

---

[15] A preliminary list of requested items is presented here. Contents, units and formats will be specified in detail by the data base manager in the call for meta-information and monitoring data.

reference will then be unique world-wide). Also method references are created in the same manner.

7. Calculation of long-term averaged concentrations

7.1 Precipitation

The yearly averaged concentration in precipitation, $\overline{C}$, should be estimated by precipitation amount weighted averaging of the concentrations for each of the sampling periods:

$$\overline{C} = \frac{\sum_{i=1}^{N} P_i C_i}{\sum_{i=1}^{N} P_i} \qquad [1]$$

where N is the number of sampling periods in one year, P_i is the precipitation amount and C_i is the reported concentration in period i.

When the concentration in a period (or part of a period) is below the measurement limit of detection (DL), the value may be reported:

1. as the observed value or computed average with the flag 0.000, if an insignificant number of input elements are non-numeric (less than 25% missing or below the detection limit). For non-continuous instruments or samplers the value must be positive and above the detection limit, for continuous monitors the value may be below the noise level or may be negative (close to zero).
2. as an estimate with the flag 0.780 if a significant number of input elements (between 25% and 50%) are missing or below the detection limit. The estimate may be negative for continuous monitors, it may be below the detection limit (but positive) for non-continuous instruments.
3. as BDL (below detection limit), where the flag is 0.781 and the value contains the detection limit (no valid numerical value is available in this case). This can also be used for aggregates where 50% or more of the input elements are missing or BDL.
4. as missing with the flag 0.999 if 50% or more of the input elements are missing or BDL (the data originator, knowing his instrument, method and the typical variations in the signal, must decide whether missing or BDL is the most correct result).

It is recommended to report the actual measured value (method 1) with a clear indication of the DL (e.g. in parentheses). When the measurement technique does not permits this, the measurements should be flagged as *below detection limit*. In the framework of EMEP and HELCOM a reporting format including instructions for exception flagging (e.g. missing data, data below detection limit) has been adopted by these organisations[16]. It is recommended to follow similar procedures in reporting CAMP data.

When data coverage is less then 75% no reliable yearly average concentration can be calculated. During evaluation of data coverage concentrations below detection limit should be seen as *missing data.* In the evaluating of averages, the actual observed values

[16] See Krognes T, Gunstrøm T.Ø. and Schaug J. (1995) Air Quality databases at NILU. EBAS version 1.01. Report TR3/95, NILU, Kjeller, Norway.

are used for data below detection limit; when only a flag *below detection limit* is reported, a value of 50% of the reported detection limit[17] is used in the averaging procedure, eq [1].

7.2 Ambient air and aerosol

The monthly averaged concentration in air or aerosol, $\overline{C}_m$, is estimated by numerical averaging of the concentrations for each of the sampling periods:

$$\overline{C}_m = \frac{1}{N}\sum_{i=1}^{N} C_i \qquad [2]$$

where N is the number of sampling periods in one month, and C_i is the concentration in period i.

When the concentration in a period is below the measurement limit of detection (DL), the actual measured value should be reported with a clear indication of the DL (e.g. in parentheses), see the discussion above on precipitation data. When the measurement technique does not permits this, the measurements should be flagged as *below detection limit*.

When data coverage is less then 50% no reliable monthly average concentration can be calculated. During evaluation of data coverage concentrations below detection limit should be seen as *missing data.* In the evaluating of averages, the actual observed values are used for data below detection limit; when only a flag *below detection limit* is reported, a value of 50% of the reported detection limit is used in the averaging procedure, eq [2]. A yearly averaged concentration is obtained by averaging the monthly concentrations; at least nine monthly values (75%) should be available.

8. Methodology for assessment of atmospheric inputs

The atmospheric input is a mass of a contaminant carried to the maritime area via the atmosphere. Total deposition consists of the sum of wet and net dry deposition; for (semi)-volatile compounds the net dry deposition term includes the mass which has re-volatilised from the sea surface[18].

Although the location of CAMP monitoring stations has been carefully selected and measurements are not directly influenced by inland sources, the atmospheric input to the marine area can not be calculated directly from the (land-based) measurements. For several reasons deposition estimates based on averaging the deposition flux over all monitoring stations will be in error:

- As sources of contaminants are mainly land-based one can expect that the concentrations in the more remote parts of the Convention waters will be lower than at coastal stations; the use of coastal data might lead to an overestimation of atmospheric inputs.
- For (semi)-volatile POP the dry deposition estimates based on ambient data will not include the effect of re-volatilisation.

---

[17] In earlier discussions on this point in the former ATMOS working group, a factor of 2/3 has been introduced. In agreement with the procedures of EMEP and HELCOM here a factor of 1/2 is recommended.

[18] Note that the net dry deposition term might be negative. This might be the case when some material which entered the maritime system by other pathways (e.g. wet deposition, riverine input, direct dumping) re-volatises.

- It is generally assumed that precipitation amounts at open sea are lower than at nearby land areas; the use of coastal precipitation data might lead to an overestimation of atmospheric inputs. Precipitation rates at coastal stations are extremely variable; for example, coastal stations in the United Kingdom have generally less precipitation than the stations in Norway, most probably due to orographic effects. To take this into account, and to correct for the smaller precipitation amount at open sea, a method which allows variable amounts of precipitation to be used based on 70% of the median values for coastal stations has been proposed for estimation of inputs to the North Sea.
- The CAMP monitoring stations are not regularly spaced along the coast line of the maritime area. For example, for the North Sea an averaging of deposition fluxes measured at coastal stations may over-estimate the atmospheric input due to the relatively higher network density in the southern, more polluted part of the North Sea. Other interpolation methods e.g. by inverse distance weighting, may overcome this problem but any concentration gradients from land to sea due to removal processes or due to dilution (the first point discussed above) is still not accounted for.

Since in the CAMP-network measurements are available on a monthly or 4-weekly basis only, it is not possible to separate on-shore and off-shore winds and estimate direction dependent concentrations. However, it is possible to apply a bulk gradient correction factor for each station derived from calculation with an atmospheric transport model. These *dispersion factors f(i)* are defined as the ratio of the modelled deposition flux at station *i* to the modelled deposition flux at the Convention Waters as a whole or sub-regions of it. This model-based dispersion factor can now be applied to extrapolate the measured deposition at the coastal station to the whole North Sea area and/or its sub-regions; total deposition is calculated by:

$$d_{(wet+dry)} = A\frac{\sum_{i=1}^{i=n_w} C_w(i)\, pa_{land}\ f_w(i)}{n_w} + A\frac{\sum_{i=1}^{i=n_a} C_a(i)\, v_d\ t\ f_a(i)}{n_a} \qquad [3]$$

where A is the total area of the North Sea (525,000 km^2) and/or sub-regions, n_w the number of stations with wet deposition measurements, n_a the number of stations with air concentrations measurements, v_d is the dry deposition velocity, t is the length of the period considered (here one year = 365*24*3600 s), $C_w(i)$ the weighted mean concentration in precipitation, pa_{land} is the precipitation amount and $C_a(i)$ the mean concentration in air at station *i*. $f_w(i)$ and $f_a(i)$ represent the dispersion factors for wet and dry deposition, respectively as calculated by the RIVM/TREND model As discussed above it is suggested to take for pa_{land} the median precipitation value of all the stations rather than using station specific precipitation amounts.

This procedure described above is the so-called Method 3a, more details can be found in Oslo and Paris Commissions (1994) Calculation of Atmospheric inputs of contaminants to the North Sea, 1987-1992.

9. Changes in methodology

If in future surveys there are significant changes of methodology of sampling or analysis, these should be reported to the Secretariat by Contracting Parties, together with any re-assessment of previously reported data.

Time schedule and data reporting format

Time schedule

Data measured in one calendar year should be reported in the next year according to the following time schedule:

1st April	Call for metadata issued from NILU (regarding both historic and new metadata), with instructions and supporting software as indicated in section 6.
1st June	Participants submit metadata via internet or on diskette, in specified formats.
31st August	Participants submit data via internet or on diskette, in specified formats. Transfer files shall have been checked with software supplied from NILU.
30th September	Draft report submitted from NILU, based on data submissions that have passed the formatting and consistency checks.
30th October	Participants submit completed/corrected data and metadata via internet or on diskette.
30th November	NILU submits final data report. This will probably also serve as output to the participants for the final validation of the data.

Data reporting format

Data reporting format of data deliverance is in accordance with the terms of the OSPAR/NILU CAMP Data Management Contract.

Appendix C

Description of NASA/Ames files

The NASA/Ames 1001 format has been extensively adopted around the world after its development by NASA. Here, a brief guide is given to the structure and information required in the form it is used by NILU. Accompanying this 4-page description is a list of components on page 65, a list of instrument code names on page 66, a list of data flags on page 67 and an example completed NASA/Ames file on page 69.

For stationary monitoring points the file format consists usually of 40 line initial lines containing qualifying information - metadata - followed by one line for each data point, defined as follows:

Line no.	variable	value	comment
1	NLHEAD	40 1001	Number of header and metadata lines before the data (40), plus NASA/Ames version no. (1001).
2	ONAME	e.g. Barrett Kevin	Name of data originator, i.e. person responsible for providing data, surname first, max. 132 characters.
3	ORG	e.g. NO01L, NILU, Box 100, N-2027, Kjeller, Norway	Registered organisation or laboratory code with O or L suffix to which data originator is affiliated (contact NILU for new institutions), separated by a comma from name, address, telephone, etc.
4	SNAME	e.g. Hjellbrekke Anne-Gunn	Person submitting/posting data file to database, surname first, max. 132 characters. May be the same as line 2, or can be another operator.
5	MNAME	e.g. CAMP(insert) EMEP(insert)	Mission/project name. If more than one project is to use the data, these are separated by spaces. An action must be specified, in this case "insert". This is used for new datasets. If a dataset is being updated, rather than entered for the first time the action is "update".
6	IVOL NVOL	1 1	Used to manage data. Always set to 1 1.
7	DATE RDATE	e.g. 1999 01 01 2000 04 01	DATE is the starting date for data file in YYYY MM DD, with year, month and day each separated by a space. Normally set to 1st January when 1 year of data is included, 1st January or 1st July when 6 months of data are included, or 1st month when 1 month of data is included. RDATE is latest date of data revisions or corrections
8	DX(1)	e.g. 1	Time units between data points for regular time series data, units as defined in line 9, XNAME. For example, for daily data points when XNAME is given as "days from file reference point", DX = 1 For hourly data when XNAME is given as "days", DX = fractional Julian day, i.e. 0.041667 (1/24). For hourly data when XNAME is defined as "hours from file reference point", DX = 1 For irregular time series data, e.g. monthly data where the number of days varies, DX = 0
9	XNAME(1)	e.g. days from file reference point	Description of the units and start time of each data point.
10	NV	e.g. 3	Number of variables/columns of data <u>in addition</u> to the start time, i.e. no. dependent variables. For fixed monitoring points this will typically be 3 - in addition to start time there is end time, data value and data flag. Other cases could include multiple

			mast measurements with further columns for heights.
11	VSCAL(n), n=1,NV	e.g. 1 1 1	Variable scalar(n), the factor by which each of the dependent elements must be multiplied to convert to correct units. Always use 1 for each.
12	VMISS(n), n=1,NV	e.g. 999 9999.9 9.999	The missing data label for each data element. Created by filling all digits in data format with 9. Number of decimals will vary according to resolution of reported data. The VMISS values will be entered in the data columns when data points are missing. This does not apply to the flag column for which a valid flag can always be assigned.
13	VNAME(n) n=1,NV	e.g. end_time, Julian date counted from the file reference point	
(14)		e.g. value, mm	
(15)		e.g. numflag, no unit, max 3 flags(of 3 digits each) coded into decimals	Variable name and description for each of the dependent variables, each listed on a separate line with max 132 characters. start-time is the independent variable, and is NOT declared. end_time, is the first dependent variable and must be defined with units. value is the second dependent variable (3rd column) and must be labelled with units. Units will change with component. numflag is the third dependent variable, and has no units. A list of flags is available on www.nilu.no/projects/ccc/flags.html, copied below.
16	NSCOML	e.g. 0	Number of special comment lines for data set. Special circumstances concerning this particular data file. If no comments then NSCOML = 0
	[SCOM(n), n=1,NSCOML]		Comment lines. If NSCOML = 0, no comment lines will be given, and NNCOML will follow NSCOML.
17	NNCOML	23	Number of normal comment lines to follow from here, before the data components. In the CAMP format 23 lines now follow before the data set.
18	Data definition:	EBAS_1	Does not vary.
19	Set type code:	e.g. TI	Here TI means time series, irregular. Thepossible set type codes are: TI: Irregular time series (variable increment in time, fixed position) TU: Uniform time series (constant increment in time, fixed position) SU: Spatial Uniform time series (constant increment in time, changing position with constant or variable increments) SI: Spatial Irregular time series (variable increment in time, changing position with constant or variable increments) PO: Position-related snapshot (point samples in varying positions at common time point) AR: Area-related snapshot (averages for named areas at common time point) GR: Grid-related snapshot (averages for indexed grid squares at common time point) GS: Grid-related snapshot (averages for indexed boxes in a 3-D grid at common time point) CO: Column data (LIDAR, sun-spectrometers, etc)

20	Regime:	IMG	Represents Imission, ground level/lower troposphere. Alternatives refer to emissions or model results. In CAMP, Regime is always IMG.
21	Station code:	e.g. NO0001R	Station code consists of the nation code, station sequence number, and station type code. In this example we have: Norwegian station 0001, Regional background. Possible station suffixes are: R regional background G global background U urban I industrial Contact NILU if a new station is to be used.
22	Platform code:	e.g. NO0001S	Introduced in CAMP/HELCOM/EMEP/AMAP to distinguish between Stationary or Mobile platforms at a station. Consists of nation code, sequence number and suffix S or M
23	Startdate:	e.g. 19990101	Indicates the start date for data, the variable DATE given previously in line 7, but without spaces, i.e. YYYYMMDD.
24	Timeref:	e.g. 08_00	Indicates the time of sample changes, Format is hour_minute.
25	Revision date:	e.g. 20000401	Indicates latest data revision date, the variable RDATE given previously in line 7, but without spaces, i.e. YYYYMMDD.
26	Component:	e.g. precipitation_amount	component name. Select from list on CAMP2000A CD, and repeated below, and spell exactly.
27	Unit:	e.g. mm	unit for component, matrix and regime. Select from list (CAMP2000A CD and below).
28	Matrix:	e.g. precip	choice between: precip air aerosol air+aerosol Component/matrix list below clarifies options.
29	Period code:	e.g. 1y	Reporting period. Choices are: 1mo: 1 month 6mo: 6 months 1y: 1 year (12 months)
30	Resolution code:	e.g. 1mo	Resolution of reported data. Choices are: 1h : 1 hour resolution 1d: 1 day resolution 1w: 1 week resolution 2w: 2 week resolution 4w: 4 week resolution 1mo: 1 month resolution
31	Laboratory code:	e.g. NO01L	The laboratory which produced measurement results. Consists of nation code, sequence number, and the suffix L. Contact NILU for new laboratories.
32	Instrument type:	e.g. bulk_sampler	Instrument type. Select from list on CAMP2000A CD and repeated below.
33	Instrument name:	e.g. BS14	Assign short name which is unique in the organisation, and including numbers or letters that may be incremented as new instruments are acquired. Do not alter a name, or re-use names from earlier instruments taken out of service in the

			organisation. Do not include organisation code or instrument type. The example BS14 may indicate “bulk sampler, 14”.
34	Method ref:	e.g. NO01L_precip1a	Add a unique, short, name for each method description, to the end of the organisation code in line 3.
35	Ext. lab. code:	e.g. NA	Use if external laboratory undertakes analysis. Otherwise use NA (not applicable)
36	Ext. meth. ref:	NA	Use if external laboratory undertakes analysis. Otherwise use NA (not applicable)
37	Add. qualifier	e.g. 1d	Insert sampling resolution, if different from reported Resolution Code, line 30.
38	File name:	e.g. TI.IMG.NO0001R.NO0001S.19990101.2000.04.01.precipitation_amount.precip.1y.1mo	Indicates location, dates, component and time resolution
39	File name ext:	e.g. .NO01L.bulk_sampler.BS14.NO01L_precip1a.NA.NA.1d	Indicates laboratory and methods. Both File name and File name ext. are constructed from the metadata elements as shown.
40		Start_time end_time value	numflag Title line of data set. Independent variable listed first (start_time) followed by the dependent variables VNAME in line 13.

Component/Matrix List: (new components are added regularly. Please contact for any not listed here).

List of data flags used in the CAMP/HELCOM/AMAPEMEP data base

Flags are sorted according to severity. Flags above 250 indicate an exception that has invalidated or reduced the quality of the data element. These may be assigned at data source or by the data originator. Flags below 250 are assigned by NILU. They indicate that the element is valid, even if it may fail simple validation tests. The value may for example be extreme, but has been tested and found correct. Up to three flags can be assigned to each data element, coded into decimals, e.g. 0.678657568

The flag 100 is used to indicate that a value is valid even if an exception in the 999-250 range has also been flagged. In this case the 100 flag must appear before other flags. In all other cases, the most severe flag should appear first if more than one flag is needed.

Flag	Mnemonic	Description
Group 9: Missing flags		
999	MMU	Missing measurement, unspecified reason
990	MSN	Precipitation not measured due to snow-fall. Needed for historic data, should not be needed for new data
980	MZS	Missing due to calibration or zero/span check
Group 8: Flags for undefined data elements		
899	UUS	Measurement undefined, unspecified reason
890	UNP	Concentration in precipitation undefined, no precipitation
Group 7: Flags used when the value is unknown		
799	MUE	Measurement missing (unspecified reason), data element contains estimated value
784	LPE	Low precipitation, concentration estimated
783	LPU	Low precipitation, concentration unknown
781	BDL	Value below detection limit, data element contains detection limit
780	BDE	Value below detection limit, data element contains estimated value. Also used for aggregates that is uncertain since many input elements were below the detection limit
771	ARL	Value above range, data element contains upper range limit
770	ARE	Value above range, data element contains estimated value
750	ALK	H+ not measured in alkaline sample
701	LAU	Less accurate than usual, unspecified reason. (Used only with old data, for new data see groups 6 and 5)
Group 6: Mechanical problem		
699	LMU	Mechanical problem, unspecified reason
679	LUM	Unspecified meteorological condition
678	LHU	Hurricane
677	LAI	Icing or hoar frost in the intake
659	LSA	Unspecified sampling anomaly
658	LSV	Too small air volume
657	LPO	Precipitation collector overflow. Heavy rain shower (squall)
656	LWB	Wet-only collector failure, operated as bulk collector
655	LMI	Two samples mixed due to late servicing of sampler. Estimated value created by averaging
654	LLS	Sampling period longer than normal, observed values reported
653	LSH	Sampling period shorter than normal, observed values reported
649	LTP	Temporary power fail has affected sampler operation

Group 5: Chemical problem

599	LUC	Unspecified contamination or local influence
593	LNC	Industrial contamination
591	LAC	Agricultural contamination
578	LSS	Large sea salt contribution (ratio between marine and excess sulphate is larger than 2.0)
568	LSC	Sand contamination
567	LIC	Insect contamination
566	LBC	Bird droppings
565	LPC	Pollen and/or leaf contamination
549	LCH	Impure chemicals
540	LSI	Spectral interference in laboratory analysis
532	LHB	Data less accurate than normal due to high field blank value
531	LLR	Low recovery, analysis inaccurate
521	LBA	Bactericide was added to sample for storage under warm climate

Group 4: Extreme or inconsistent values

499	INU	Inconsistent with another unspecified measurement
478	IBA	Inconsistency discovered through ion balance calculations
477	ICO	Inconsistency between measured and estimated conductivity
460	ISC	Contamination suspected
459	EUE	Extreme value, unspecified error
458	EXH	Extremely high value, outside four times standard deviation in a lognormal distribution
457	EXL	Extremely low value, outside four times standard deviation in a lognormal distribution
456	IDO	Invalidated by data originator

Group 2: Exception flags assigned by the database co-ordinator (NILU)

299	CNU	Inconsistent with another unspecified measurement
278	CBA	Inconsistency discovered through ion balance calculations
277	CCO	Inconsistency between measured and estimated conductivity
260	CSC	Contamination suspected
259	CUE	Unspecified error expected
258	CXH	Extremely high value, outside four times standard deviation in a log-normal distribution
257	CXL	Extremely low value, outside four times standard deviation in a log-normal distribution
249	QDT	Apparent typing error corrected
211	QDI	Irregular data checked and accepted by database co-ordinator
210	QDE	Episode data checked and accepted by database co-ordinator

Group 1: Exception flags for accepted, irregular data

147	QOD	Below theoretical detection limit or formal Q/A limit, but a value has been measured and reported
120	QOR	Sample reanalysed with similar results
111	QOI	Irregular data checked and accepted by data originator
110	QOE	Episode data checked and accepted by data originator
100	QOU	Qualified by data originator

Example NASA/Ames file:

This is simply an example, constructed from the explanatory comments above. Most variables should be altered to suit the component, location, time period, etc. in question. The unchanging elements are lines 6, 17, 18, 20 and 36. Some others rarely change, e.g. line 1 and line 35. Others will vary and should certainly be checked carefully for each data submission, as should the data block itself, including start_time and end_time. Similar templates for different time resolutions etc. can be found on the CAMP2000A CD.

Appendix E

CAMP Data: Excel files on OSPAR website

Comprehensive Atmospheric Monitoring Programme
Observations From Coastal Stations
Report for 1999

ADDITIONAL NOTE ON Appendix E - CAMP Data, 1987 - 1999.

Norwegian Institute for Air Research
NILU Report OR 2/2001, June 2001.

The present dataset for 1987-99 accompanies the 1999 data report. The report and accompanying dataset was presented to the OSPAR Working Group on Inputs to the Marine Environment (INPUT) at London, January 2001. All parties were asked for comments and updates to the dataset. The dataset presented here represents the result of this and earlier data validation rounds. This also represents the CAMP data as currently reported to the OSPAR database.

The data values recorded in the OSPAR database are here presented under headings of country, and thereafter individual station numbers. Data is supplied as Excel workbooks for each station for which data is held on the database. Each workbook contains a separate sheet for each dataset held on the database. These are arranged alphabetically. Separate datasets are held where measurement methods have changed at a station. These are listed sequentially, e.g. cadmium(1), cadmium(2) etc.

Stations are identified by code number. Lists of stations, their latitude and longtitude, height above sea level and distance from the coast are contained in the accompanying Excel table entitled 'station_list.xls'. Which stations have monitored which components at which time are described in three excel tables entitled 'nitrogen_component_list.xls', 'organics_component_list.xls', and metals_component_list.xls'. These are intended as a guide in locating particular compound data. It should be noted that currently all data from the German stations DE0001 Westerland and DE0041 Westerland Tinnum are listed as DE0001.

Not all of the historical data listed in the early CAMP Data Reports is held on the database. For such data much accompanying metadata concerning methods, etc may be missing. Often precise dates are missing. For completeness the historical data reports are included as released earlier by OSPAR. The reader should refer to these if interested in earlier time periods.

Data originators in each country are encouraged to review both the Excel datasheets, and the historical data reports and report any additional information to NILU. Particularly, data originators are requested to provide or update methods information, instrument information, and laboratory information. Updates should be reported by email to:

anne-gunn.hjellbrekke@nilu.no *or*
kevin.barrett@nilu.no

ABSTRACT
This report describes the observations made at monitoring stations in 1999 around the North Sea and North East Atlantic by the CAMP programme. The monitoring programme and stations are described and annual observed values given in summary, supported by actual observed values listed in the Appendix.
