Dumping of Wastes at Sea in 2000

**OSPAR Commission
2003**

The Convention for the Protection of the Marine Environment of the North-East Atlantic (the “OSPAR Convention”) was opened for signature at the Ministerial Meeting of the former Oslo and Paris Commissions in Paris on 22 September 1992. The Convention entered into force on 25 March 1998. It has been ratified by Belgium, Denmark, Finland, France, Germany, Iceland, Ireland, Luxembourg, Netherlands, Norway, Portugal, Sweden, Switzerland and the United Kingdom and approved by the European Community and Spain.

La Convention pour la protection du milieu marin de l'Atlantique du Nord-Est, dite Convention OSPAR, a été ouverte à la signature à la réunion ministérielle des anciennes Commissions d'Oslo et de Paris, à Paris le 22 septembre 1992. La Convention est entrée en vigueur le 25 mars 1998. La Convention a été ratifiée par l'Allemagne, la Belgique, le Danemark, la Finlande, la France, l'Irlande, l'Islande, le Luxembourg, la Norvège, les Pays-Bas, le Portugal, le Royaume-Uni de Grande Bretagne et d'Irlande du Nord, la Suède et la Suisse et approuvée par la Communauté européenne et l'Espagne.

ASSESSMENT OF THE ANNUAL OSPAR REPORTS ON DUMPING OF WASTES AT SEA IN 1999 AND 2000

Introduction

Assessments of the OSPAR Reports on Dumping of Wastes at Sea should aim at identifying issues of concern related to data and information reported by Contracting Parties. They also should examine whether requirements of the OSPAR Guidelines for the Management of Dredged Materials (OSPAR agreement reference number 1998-20) and of the reporting formats (OSPAR agreement reference number 1996-1 (now superseded) and 2002/1) are fulfilled. A further issue of the assessment consists in providing reliable data on contaminant inputs to the OSPAR maritime area. Furthermore, the assessment should examine, whether trends of the amounts of dredged material dumped and the associated contaminant loads can be established.

All Contracting Parties (CPs) provided data on amounts of wastes dumped at sea for 1999, and for 2000. However due to late submission, Portugal's data for 2000 have not been taken into account in this assessment. In 1999, dredged material dumped at sea by Portugal only amounted to about 2% of the total quantity disposed of by all Contracting Parties. Therefore the lack of this information may not have much influence on the assessment of amounts disposed of.

However, information provided on contaminant loads often was not complete. 3 Contracting Parties did not report on contaminants at all, with the exception of few odd values. 6 CPs in 1999 and 7 CPs in 2000 provided complete data sets for trace metals, however only 2 complete data sets were received for organic contaminants. 3 CPs submitted organic contaminant loads only for part of the disposal sites.

France, Spain and the United Kingdom provided the additional information requested in the reporting format. However, additional information on analytical methods was available from the replies to the Questionnaire on Methods of Analysis of Sediments (SEABED 02/2/6). For trace metals analyses, on the one hand, different methods are used, which may result in systematic differences of measured concentrations in case total (coarse-grained) samples are analysed, and on the other hand, total samples or fine fractions are analysed. This may result in a lack of comparability for trace metal data provided by different CPs, and consequently in a large uncertainty of total trace metal loads. In principle, methods applied for organic contaminants and organotin compounds should give comparable results, however the reported differences in detection limits may influence the estimation of loads, as often concentrations of organic contaminants below detection limits are reported.

In order to assess the effectiveness of measures to reduce the quantities of dredged material as well as the associated contamination, it might be worth examining trends in the amounts dumped and contaminant inputs over a period of several years. At present, only the amounts dumped from 1995 - 2000 are comparable and can be examined, as the reporting requirements changed from wet weight of dredged material to dry weight only in 1995. As mentioned above, it may be even more difficult to establish trends in contaminant loads of dredged material due to incomplete data sets and a lack of comparability of data provided by different CPs. Currently, only a rough comparison can be carried out.

Permits

Table I of the Annual OSPAR Reports on Dumping of Wastes at Sea summarises the numbers of permits issued and the tonnes licensed for the different types of wastes dumped. The amounts actually disposed of are summarised in Table II and Table III. Although still several types of wastes are dumped, most of the permits were issued for dredged material, as in previous years: about 80% of the permits and more than 99% of the overall amount licensed for disposal at sea refer to dredged material. Disposal of 113 500 t and 280 000 t of inert material was permitted by Norway in 1999 and 2000. In 1999 and in

2000, a total of about 160 t fish waste each year was permitted for sea disposal by UK, and UK and Ireland, respectively. In addition Norway disposed of 200 t of fish meal in 2000. Norway also reported on a permit for disposal of 30 t of steel wire waste. The number of vessels licensed for disposal was much higher than in previous years: 33 and 34 licenses were issued in 1999 and 2000, whereas in previous years at maximum 18 vessels (1996) were dumped.

As in previous years, a comparison of the permits and the amounts of dredged material licensed in 1999 and 2000 reflect the different licensing procedures of the Contracting Parties (Table I of this assessment). Some CPs issue few permits for large amounts of dredged material, e.g. Belgium and the Netherlands with 5 permits for more than 10 Million t of dredged material, and on the other extreme, Norway issued more than 50 issues for about 600 000 t. In other Contracting Parties, a general permit (Iceland) or no formal permits are issued (Germany) or reported (Spain, Sweden).

Specific reporting on dumping permits

Only Norway specifically reported on permits for the disposal of vessels in both years, 1999 and 2000. However, it should be kept in mind, that at present not all Contracting Parties report on or issue permits. With the adoption of the new reporting format, also operations regulated by other means than licenses should be reported, and possibly, more information will be provided in future. Specific reporting may also be incomplete, since not all Contracting Parties have established national action levels yet.

Amounts of dredged material dumped

As disposal of dredged material may have physical impacts on the marine environment, total amounts of material disposed of are included in the assessment (Tables II and III). As in previous years, more than 90% of the dredged material reported to OSPAR were dumped by only 5 Contracting Parties (Belgium, France, Germany, The Netherlands, UK).

As the amounts of material to be dredged are strongly influenced by natural conditions, the dumping strategy, and capital dredging activities, trends in the amounts dumped may be difficult to observe. The overall amounts of material disposed of vary significantly from 1995 - 2000, however no trend can be observed.

Variations in national amounts dumped often are more distinct (Fig. 1 a and b). In the UK, quantities disposed of increased from about 20 million t dredged material from 1995 – 1998 to 32 million t in 1999, and decreased to about 17 million t in 2000, again. This peak in 1999 mainly is caused by one large capital dredging operation with about 17 million t dredged material. Also in Germany, capital dredging in the Elbe estuary gives rise to 6 million t in addition to 7 million t from maintenance dredging as usual. In the Netherlands, variations of the amount of material dredged possibly are due to various amounts of dredged material from Rotterdam Harbour. Whereas quantities disposed of in Sweden decreased significantly from 1995/1996 to 1999/2000 by about a factor 20, in Denmark an increase by a factor 5 can be found.

For most Contracting Parties, the bulk of dredged material originates from maintenance dredging. In 1999/2000, appreciable amounts of material from capital dredging, i.e. more than 10%, were reported by Belgium, Iceland, Ireland and the UK, and in addition, in 2000 by Germany and Spain. In Iceland, all the material came from capital dredging, whereas in Denmark, France, The Netherlands, Norway and Sweden no or only very small amounts originate from capital dredging. For the UK, the proportion of capital dredging is difficult to estimate, as often both, capital and maintenance dredging is indicated without giving the ratio of the respective amounts. However, in 1999 and 2000, about 18 and 3,2 million t, i.e. more than 50% and about 20% of the dredged material, respectively, are attributed to a single capital operation.

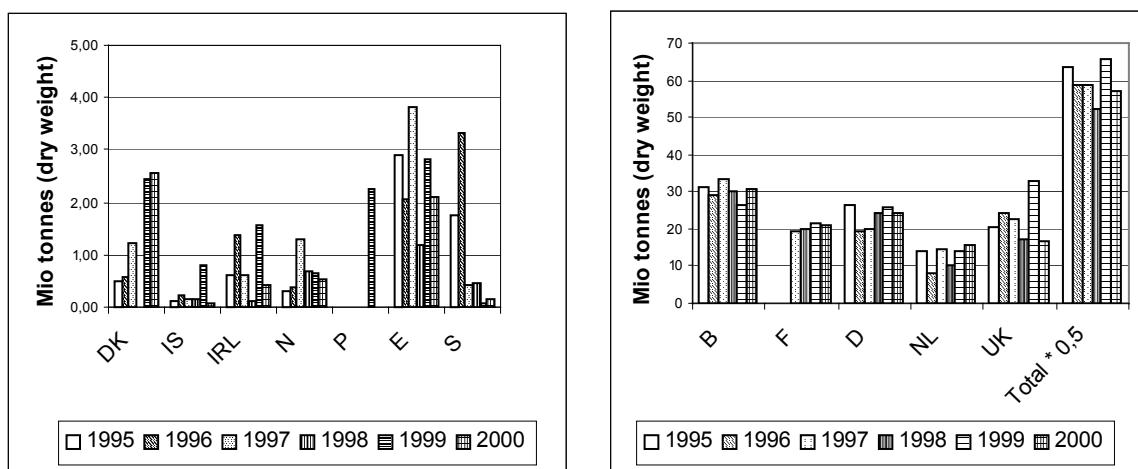

Fig. 1a and 1b: National and total amounts of dredged material disposed of from 1995 to 2000

In order to have one y-axis for all amounts, the total amount of dredged material for all CPs was multiplied by a factor of 0,5.

In addition, a separate evaluation of the amounts dredged in harbours on the one hand and in estuaries/sea channels on the other hand is carried out (cf. Tables IV and V). Contracting Parties often indicated more than one type of area dredged per dumping operation, but usually the reports did not include information on the percentages of dredged material associated with the respective types. When both, harbours and estuaries/sea channels, are indicated as origin of the dredged material without the respective percentages, usually 50% were attributed to harbours and 50% to estuaries/sea channels. These amounts assigned to harbours and to estuaries/sea channels have large uncertainties.

Similarly as from 1995 to 1998, the quantities of dredged material from estuaries or sea exceeded those from harbours significantly in 1999 and 2000, and the ratio of material from harbours to that from estuaries/channels is quite constant. However, compared to years before 1994, the relative amount of dredged material from estuaries/sea channels increased (Table VI).

It is difficult for Contracting Parties to distinguish exactly the contribution from the 3 categories. However, on the basis of reported data the total quantities of dredgings summed for all CPs from estuaries/sea channels exceeded those of harbours, although the distribution is quite different for Contracting Parties. The bulk of dredged material in Belgium, Germany and to a minor extent in France originates from estuaries and sea channels, whereas Iceland, The Netherlands and Norway only reported on dredged material from harbours. This distribution was quite constant over the last 6 years. For most of the other Contracting Parties, larger amounts of material came from harbours than from estuaries/sea channels. In 1999/2000 for most Contracting Parties the ratios of dredged material from harbours to that of estuaries/sea channels were similar as in previous years. However, in the UK this ratio decreased significantly from about 6 in 1995/1996 to 1,3 in 1999/2000. This may be due to the influence of large capital dredging projects in particular years.

As already observed in previous years, the number of dumping sites compared to the amounts dumped differs strongly for the Contracting Parties (cf. Table I). Belgium, France, Germany and the Netherlands disposed of much large quantities of dredged material per disposal site (e.g. in 1999: 12, 30, 20 and 8 dumping sites for about 26 Mt, 21 Mt, 26 Mt and 14 Mt of dredged material), whereas the ratio of the amount of dredged material to the number of dumping sites was considerably smaller in other Contracting Parties. In 1999, Norway and Sweden e.g., disposed of about 0,6 Mt and 0,09 Mt dredged

material at 14 and 9 dumping sites, respectively. This indicates that some of the dumping sites receive much higher amounts of dredged material than others. However, the dumping reports do not include information on the sizes of disposal sites, and these may differ. It is recommended that the evaluation of impacts on the seabed should be based on the monitoring reports.

Total contaminant loads

In 1999 and 2000, 6 or 7 CPs provided complete data sets on trace metal loads, and 1 or 2 further CPs submitted data only for part of the dumping sites. For most dumping sites without data for contaminant loads, there was no information whether the dredged material was exempted from analyses according to the OSPAR Dredged Material Guidelines or whether required data were not reported. This information would support data assessment, as contaminant loads of material exempted from analyses are negligible in contrast to contaminant loads of material that might be contaminated to varying degrees.

Nevertheless, trace metal data are considered to be sufficient for an assessment. However, it should be kept in mind that due to differences in the analytical approaches, as mentioned in § 4, comparison of national total trace metal loads between CPs may be associated with large uncertainty. Therefore, the overall total trace metal load for all CPs can be only regarded as rough estimate, to have an indication of the order of magnitude of loads.

For organic contaminants and TBT, no proper assessment can be carried out, as both, in 1999 and 2000, only little information on these contaminants is available. Contracting Parties often only reported on few organic contaminants and/or on selected dumping sites. As the Dredged Material Guidelines which introduced the requirement of analyses of organic contaminants, came into force only in June 1998, a more complete reporting on these compounds should be expected in future.

National total contaminant loads associated with dredged material are summarised in Tables II and III. Loads which could not be estimated reliably due to a lack of data are identified with brackets and italic letters. When concentrations below detection limits are reported, these values divided by 2 are used for further calculations.

Trace metal loads

For most CPs, national trace metal loads reported for 1999 and 2000 are quite similar. However, national loads estimated for Ireland and the UK in 2000 are significantly lower than those in 1999. At the same time, the quantities of dredged material disposed of in these countries decreased strongly.

Comparison between the current data from 1999/2000 with national loads reported for 1997 and 1998 showed a few considerable differences:

- For a few trace metals, loads reported by Belgium in 2000 and in 1997 seem to be up to a factor 2 - 5 higher than those reported for 1998 and 1999. However, it should be taken in account that in 1998 and 1999, no information on loads for internal dumping sites have been submitted. Dredged material disposed at these sites amounts to about 50% of the total quantities dumped. Furthermore, for some trace metals loads reported in 2000 as well as the corresponding concentrations are even higher than in 1997. This is probably due to new disposal sites which are located close to Antwerp Harbour.
- In Germany, trace metal loads reported for 1999 and 2000 cannot be compared to previous years because reporting of contaminant loads for 4 of the disposal sites in estuaries and navigation channels, which constitute most of the material dredged only started in 1999.
- In The Netherlands, the national totals for all trace metals in 1998 were almost a factor 2 lower than in 1997, 1999 and 2000. This difference is probably caused by dumping larger amounts of dredged material from the Rotterdam harbour in 1997, 1999 and 2000 compared to 1998.

- In 1999 and 2000, the UK reported arsenic loads which are significantly higher than in earlier years. However, this was due to a greater proportion of the dredged material being analysed for arsenic.

A comparison of the sums of the national total loads from 1995 to 2000 shows some variability, both for the total loads, and for specific total loads, i.e. total loads per e.g. 1 million tonnes, too (Fig. 2a). In 2000, specific total loads of most trace metals are higher than in 1999. Furthermore, these loads seem to be slightly higher in 1999/2000 than in 1997/1998. The apparent increase of all trace metal loads partially may be caused by additional reporting for large amounts of dredged material in Germany, and by additional reporting of loads from dredged material in Belgium disposed of at new disposal sites close to Antwerp Harbour. In addition, particularly, arsenic loads are higher in 1999/2000 than in earlier years, probably due to the aforementioned high loads reported by the UK.

Data are not considered to be sufficient for deriving a trend, especially having in mind that contaminant loads reported often were incomplete and are associated with large uncertainties. Furthermore, as data were lacking for France in 1995/1996, they were assumed to equal those in 1994. The use of these data might bias the comparison of contaminant loads slightly.

Comparative Contaminant Loads from Harbours and Estuaries / Sea Channels

As total contaminant loads may be influenced strongly by varying amounts of dredged material from areas with a different degree of contamination, trends probably can be established only, if long time series are available. In addition, trends in total contaminant loads of dredged material are not regarded as appropriate means to assess the effectiveness of measures for the reduction of contaminant inputs, as these loads include natural background contamination and may count in and even more than once those quantities that have been merely relocated and do not constitute new input. A trend assessment should focus on the new contaminant input, however, there is no agreed approach for its estimation available yet.

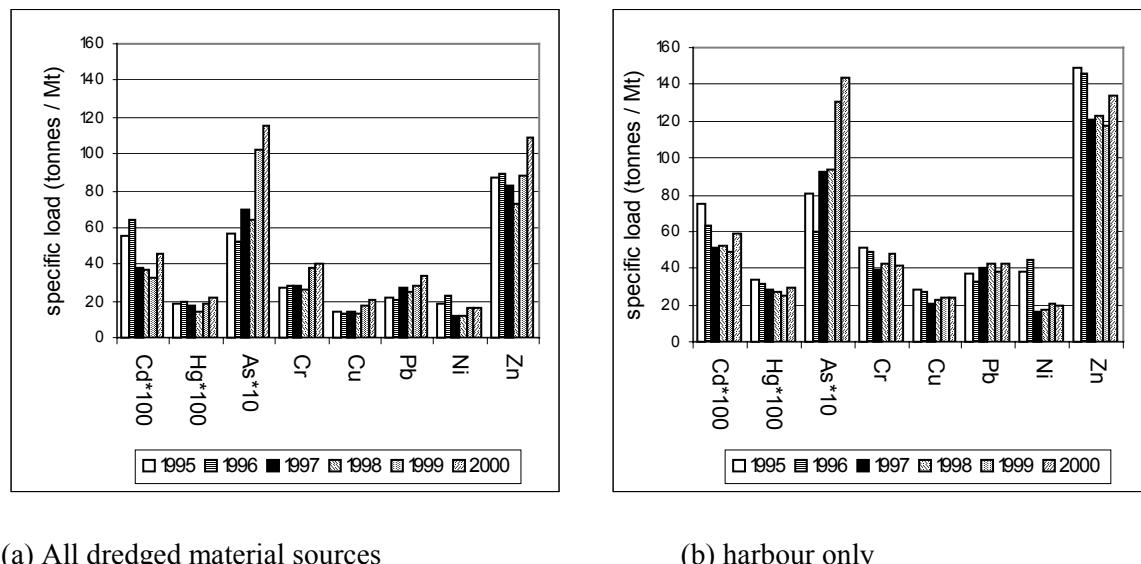

In order to reduce variability due to the relocation of large amounts of dredged material and the associated contaminants within estuaries and sea channels, and to make the identification of a potential trend more likely, contaminant loads from harbours and from estuaries and sea channels are assessed separately. However, as mentioned earlier, often both, dredged material from harbours as well as from estuaries and sea channels are disposed of at same disposal sites, and as the respective percentages usually are not indicated, 50% each, are attributed to harbours and to estuaries/sea channels, as an estimate. This rough estimate may add to the uncertainty of the assessment of contaminant loads from harbours significantly.

Furthermore, it is assumed, that usually dredged material relocated in estuaries and sea channels repeatedly only contribute to a minor extent to the new contaminant input compared to dredged material from harbours. However, it is recognised, that this approach is associated with large uncertainties. For example, some industrialised estuaries may need to be considered as potentially having similar effects to harbour dredgings as they may contribute to new contaminant inputs.

Tables IV and V give the contaminant loads separately for harbours (Tables IV a, V a) and for estuaries and sea channels (Tables IV b and V b).

Contaminant loads from harbour dredgings summed for all CPs are similar for both years, and they show a similar variability as the total loads. In Fig. 2, specific loads (i.e. tonnes of a trace metal / million tonnes of dredged material) from harbour dredgings since 1995 are compared with specific total loads from all dredged material sources. Patterns of loads from harbour dredgings and total loads are similar. Except the high arsenic loads in 1999/2000 (c.f. § 22) and a decrease of Ni loads by about 50% compared to 1995/1996, no significant trend can be established for harbour dredgings.

In 1999 and 2000, the mean percentage of trace metal loads in dredged material from harbours amounts to about 40 - 50% of the reported total trace metal loads. The percentage is very similar for all trace metals and both years, and also similar to results from 1997/1998. However, the 50% - 60% from estuaries / sea channels is contained in approximately double the volume of dredged material from harbours.

(a) All dredged material sources

(b) harbour only

Figures 2a and 2b: Specific total trace metal loads from all dredged material sources and specific loads of trace metals from harbour dredgings in 1995 to 2000

In order to have one y-axis for all trace metals, loads of Cd and Hg were multiplied by a factor of 100, and the As load was multiplied by a factor of ten for presentation in Figure 2.

Since the contaminant input to the OSPAR maritime area by dredged material estimated from total loads is overestimated, the former reporting formats required information on environmentally relevant loads in addition to total loads. However, these loads were only reported by the Netherlands for the dredged material from their harbours. The procedure for estimating environmentally relevant loads takes into account natural background concentrations of natural occurring substances (see SACSA 20/2/3-E).

The environmentally relevant loads estimated by the Netherlands for 1999/2000 only amount to about 20 - 40% of the total loads for Cd, Hg, As, Pb and Zn, and to about 0% - 5% for Cr, Cu and Ni. These results confirm that actual metal inputs may be considerably overestimated, if background concentrations are not taken into account. Particularly for Cr, Cu and Ni, the dredged material did not introduce a significant new load to the sea. For oil, the environmentally relevant load was about 20 - 50% of the total, and for PAHs by about 70% of the total load. For organochlorine and organotin compounds, the natural background concentrations are assumed to be zero, and the environmentally relevant load correspond to the total loads.

Conclusions

There are still small amounts of several wastes other than dredged material disposed of at sea (see Tables II and III).

Disposal sites receive significantly different amounts of dredged material. It is recommended that the evaluation of impacts on the seabed should be based on monitoring reports.

No trend could be established for total amounts of dredged material summed for all CPs. However, separate evaluation of amounts for individual CPs indicated some changes.

For a reliable trend assessment it would be preferable to perform a separate assessment on the one hand for the amounts of dredged material from harbours and of dredged material from estuaries / sea channels, and on the other hand for maintenance and capital dredgings. However, at present dumping reports do not include sufficient information for a proper separation.

Trends could be established neither for total contaminant loads nor for loads from harbour dredgings. At present, data are not considered to be sufficient for deriving a trend of total contaminant loads, especially having in mind that contaminant loads often are reported incompletely, and that they are associated with large uncertainties. Particularly for organic contaminants and TBT, there is a lack of information.

Furthermore, trend assessment of total contaminant loads are not regarded as appropriate means to evaluate the effectiveness of measures for the reduction of contaminant inputs due to the disposal of dredged material at sea.

As demonstrated by The Netherlands, background contamination contributes significantly to total trace metal loads.

GENERAL INFORMATION

The continental decimal system is used throughout this report. Empty cells indicate that no information was available. Italic numbers are used when the measured/calculated value was smaller than the actual number given in the cell.

ADDITIONAL INFORMATION

(Referring to Part II of the Formats for the Annual Reporting of Amounts of Wastes Dumped at Sea adopted at PRAM 1995)

(1) Giving the area a code number:

Enter the code number for the dumping area according to the following format:
F/(3 figures representing the department number)(2 figures representing the area within the department)

(2) Name of dumping site:

Local name for site (principal port connected thereto)

(3) Positioning of dumping site:

Position 1: Upstream of the limit of the sea

Position 2: Upstream of baseline (inner maritime waters)

Position 3: Downstream of baseline (territorial waters)

Reminder: The baselines are the low water mark and the straight baselines (particularly in the case of indented coasts and those with offshore islands) and the lines closing the bays which are determined by Decree.

The width of France's territorial waters is fixed at 12 nautical miles. The transverse limit of the sea in the estuaries is the artificial limit of separation of sea and river which is defined by the administration.

(4) Method used:

Code	Method
1	stationary dumping while at anchor
2	dumping while in motion
3	discharge by pipeline

(5) Depth:

Measured with regard to Nautical Chart reference (0 Nautical Chart or 0 low water in estuary).

(6) Position:

Position of a point representative of the dumping area.

(7) Plan to be supplied:

Position of the dumping area on a Nautical Chart extract, with details of the coordinates of the characteristic points defining the area.

Ireland

An additional three, not previously used, sites have been used in 2000 – IRL 34, 35 & 36. Their positions are given in Table 1 of Figure 5.

Portugal

Areas of Dumping at Sea:

Code	Areas	Zone	Dumping points		Category of material	Quantity

United Kingdom

DM001 was a deposit site at Harrington Harbour off the North-West coast of England.

2. METHOD OF DETERMINATION

France

Definition of assumptions made in calculating quantities of dry matter in table 3a

Relationship between the saturated density of the mixture ρ_{sat} and the concentration of dry matter ρ_{ms} :

These two parameters are connected through the following relationship:

$$\rho_{ms} = \frac{\rho_{ss}}{(\rho_{ss} - \rho_o)} \times (\rho_{sat} - \rho_o) \text{ in which:}$$

- ρ_{sat} = density of the mixture (in kg/m³)
- ρ_{ms} = concentration of dry matter in the mixture (in kg dry matter/m³)
- ρ_o = density of water at 4°C (in kg/m³)
- ρ_{ss} = density of the dry sediment (in kg/m³).

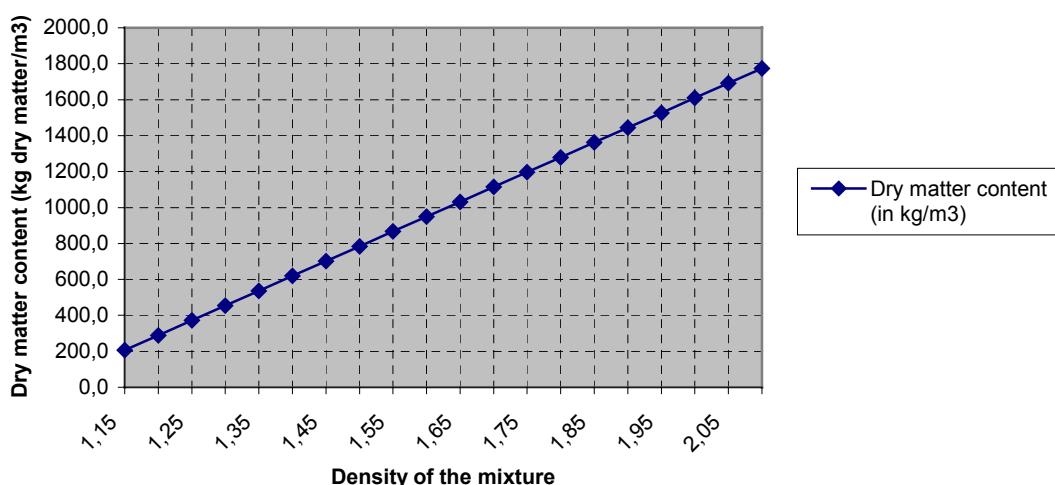

Assuming that $\rho_{ss} = 2\,600 \text{ kg/m}^3$ and $\rho_o = 1\,025 \text{ kg/m}^3$, the following simplified formula is obtained:

$$\rho_{ms} = 1\,650,8 \times (d - 1\,025)$$

where d is the density of the mixture.

This can be represented graphically as follows:

Estimation of dry matter content as a function of the density

Calculation of quantities of dry matter deposited

If the volume in situ to be dredged is known, an approximate calculation of the quantities of dry matter dredged can be carried out using the following assumptions according to the situation encountered:

Type of material	Mean density in situ	Density for calculation	Dry matter content (kg dry matter/m ³)
Fresh sludge	1,1 to 1,3	1,2	288,9
Consolidated sludge	1,3 to 1,6	1,45	701,6
Sand	1,6 to 2	1,8	1 279,4

In practice, data relating to the mean densities in situ of the sediments dredged in the principal French ports are known and listed by the Groupement d'Intérêt Economique Dragages-Ports (Port-dredging Economic Interest Grouping).

If the volume in the hoppers is known, an approximate calculation of the quantities of dry matter dredged can be carried out using the following assumptions according to the situation encountered:

Type of dredging	Type of material	Mean density in the Hoppers	Density for calculation	Dry matter content (kg dry matter/m ³)
Trailer suction dredge	Liquid sludge	1,2	1,2	288,9
	Consolidated sludge	1,25 to 1,35	1,3	454,0
	Sand	1,8	1,8	1 279,4
Mechanical dredge	Fresh sludge	1,15 to 1,25	1,2	288,9
	Consolidated sludge	1,3 to 1,4	1,35	536,5
	Sand	1,8	1,8	1 279,4

Spain

With regard to the grain size fraction analysed, in all cases has been smaller than 0,063 mm, apart from the analysis of the deposit sites E/8 (Villagarcía), done with a smaller 2 mm than fraction.

With respect to the methods of determination used, they have been the following ones:

Sample preparation

- Drying of the sample at 60°C during 24h.
- Sieving of the sample with a 2 mm sieve.
- Separation, when done, of the smaller than 0,063 mm fraction, using water and a 0,063 mm plastic sieve.
- Homogenisation and grinding of the sample in an agate mortar.
- Determination of the humidity by drying at 105°C up to constant weight.

Heavy metals analysis

For Cd, Pb, Cu, Zn, Ni and Cu:

- Acid digestion with nitric acid in a microwave oven.
- Quantitative determination by atomic absorption spectrophotometry, in flame or in graphite chamber, depending on the sample concentration.

For As:

- Acid digestion in microwave oven with nitric acid.
- Previous reduction of the sample.
- Determination by hydride generation matched to an atomic absorption spectrophotometer.

For Hg:

- Acid digestion in microwave oven with nitric acid.
- Determination by cold steam technique matched to atomic absorption spectrophotometry.

Poly-chlorinated-biphenyls

- Extraction of homogenised and grinded sample with a methylene chloride:hexane (1:1) mixture.
- Extract concentration and passing through an anhydrous sodium sulphate column.
- Sulphur elimination by purification with powder of copper.
- Extract purification in column, avoiding the organochlorated compounds with a mixture of ethylic ether in hexane at successive concentrations of 6, 15 and 50%, ending with pure hexane.
- Quantitative determination by gas chromatography with electron capture detector, using an HP-S capillary column of 0,22 mm inner diameter.

Polyaromatic hydrocarbons

- Extraction by means of decantation, mixture with acetone:hexane (1:1) and ultrasounds.
- Purification by means of decantation with salt saturated with sodium sulfate.
- Determination using gas chromatography with a 60 mm capillary column, BOD5 and flame ionization detector.
- Confirmation, when necessary, by means of mass chromatography.

Organic matter

For this parameter we have used two types of techniques.

As volatile solids:

- Drying of the sample at 105°C, grinding in a mortar and combustion in muffle at 550°C up to constant weight.
- Determination of total quantity as (formula used in our "Recommendations for the management of dredged material in the ports of Spain"):

$$TOC \text{ mass (tn)} = \frac{0,35 \times \text{Volatile solids concentration (\%)} \times \text{dumped mass (tn)}}{100}$$

As Total organic carbon (TOC):

- Drying at 105°C, elimination of the inorganic carbon with HCL and determination by means of calcination and detection of CO₂ with an infrared detector (Elementary analysis).
- Determination of the total quantity as:

$$TOC \text{ mass (tn)} = \frac{TOC \text{ concentration (\%)} \times \text{dumped mass (tn)}}{100}$$

United Kingdom

All analyses of dredged material on <2mm fraction. Methods of determination as specified in reports listed below:

Allchin, C.A., Kelly, C.A. and Portmann, J.P. (1989) Methods of analysis for chlorinated hydrocarbons in marine and other samples. Aquatic Environmental Protection: Analytical Methods, MAFF Directorate of Fisheries Research, Lowestoft, (6), 25 pp.

Jones, B.R. and Laslett, R.E. (1994) Methods for analysis of trace metals in marine and other samples. Aquatic Environmental Protection: Analytical Methods, MAFF Directorate of Fisheries Research, Lowestoft, (11), 29 pp.

Kelly, C.A., Law, R.J., and Emerson, H.S. (2000) Methods of analysing hydrocarbons and polycyclic aromatic hydrocarbons (PAH) in marine samples. Science Series, Aquatic Environmental Protection: Analytical Methods, CEFAS Lowestoft. (12), 18pp.

Law, R.J., Fileman, T.W. and Portmann, J.P. (1988) Methods of analysis of hydrocarbons in marine and other samples. Aquatic Environmental Protection: Analytical Methods, MAFF Directorate of Fisheries Research, Lowestoft, (2), 25 pp.

Waldock, M.J., Waite, M.E., Miller, D., Smith, D.J. and Law, R.J. (1989) The determination of total tin and organotin compounds in environmental samples. Aquatic Environmental Protection: Analytical Methods, MAFF Directorate of Fisheries Research, Lowestoft, (4), 25 pp.

FOOTNOTES TO ALL TABLES

Table 1

- (1) Specific permits for the dumping of dredged material are not issued in Germany but all dumping are carried out under national regulations which are in accordance with OSPAR/London requirements.
- (2) There is a general permit in Iceland for disposing dredged material when the contamination of the sediment does not exceed given threshold values.
- (3) One of the 11 Ireland permits was not activated – 38 000 tonnes (dry).
- (4) The figure for licensing is in m³ not in metric tonnes for the Netherlands.
- (5) UK licensed tonnages are usually on a wet weight basis. These are the estimated dry weight equivalents.
- (6) An additional 1 000 tonnes dry weight of fish waste was licensed for deposit in the sea in 2000. The material was licensed for deposit directly onto the intertidal zone but is not dumping under the terms of the Convention. 1 559 tonnes of fish waste was deposited under this licence during 2000.

Table 2

- (1) There is no permits issued for dredged material exceeding action level 2.
- (2) The type of inert material is fine sand. It was classified as inert under the national classification.
- (3) Norway did not report on contaminants as only minor amounts were detected.

Table 3a

- (1) New disposal sites close to Antwerp Harbour.
- (2) See “deposit site” in section 1.
- (3) For France, where necessary, the quantities have been converted from m³ into tonnes by using the conversion method explained in section 2 “Methods for determination”.
- (4) For Germany where necessary, the quantities have been converted from cubic metres into tonnes by whereby the following conversion factors (specific gravity) have been used:
 - in case of silt: 1,2
 - in case of sand: 1,8
 - in case of lacking information: 1,5
 - in cases where no dry weight (DW) was indicated, the DW was estimated to be 50% (in order to calculate the annual load from the concentration given).
- (5) The total load figures in table 3b for the sites 14, 15, 17 and 34 have been calculated on the basis of the silk fraction only.
- (6) Additional quantity of 6 081 000 t sand, exempt from chemical analysis according to § 3.3.1.
- (7) Additional quantity of 3 623 000 t sand, exempt from chemical analysis according to § 3.3.1.
- (8) Additional quantity of 800 000 t sand, exempt from chemical analysis according to § 3.3.1.
- (9) Additional quantity of 2 752 000 t sand, exempt from chemical analysis according to § 3.3.1.
- (10) NL-13a is introduced for the construction of a new harbour entrance.
- (11) For NL-14 and NL-15 no data was made available.
- (12) For Portugal, the total quantity in metric tonnes for all sites are in wet weight.
- (13) Dredged of land material for the marina.
- (14) No information available on the type, size and weight of the vessel.

Table 3b

- (15) Quantities of pesticides.
- (16) Cd, Hg, As, Cr, Cu, Pb, Ni, Zn, poly-choliranted-biphenyls, HPA total and TBT values are deducted from concentrations in the fraction of dry matter inferior to 2mm.

- (17) <DL; for concentration of poly-chlorinated-biphenyls and cadmium, detection limit is equal to 1µg/kg and 1mg/kg of dry matter fraction inferior to 2mm, respectively.
- (18) The values for metals are in mg/Kg and for organic compounds in µg/Kg.

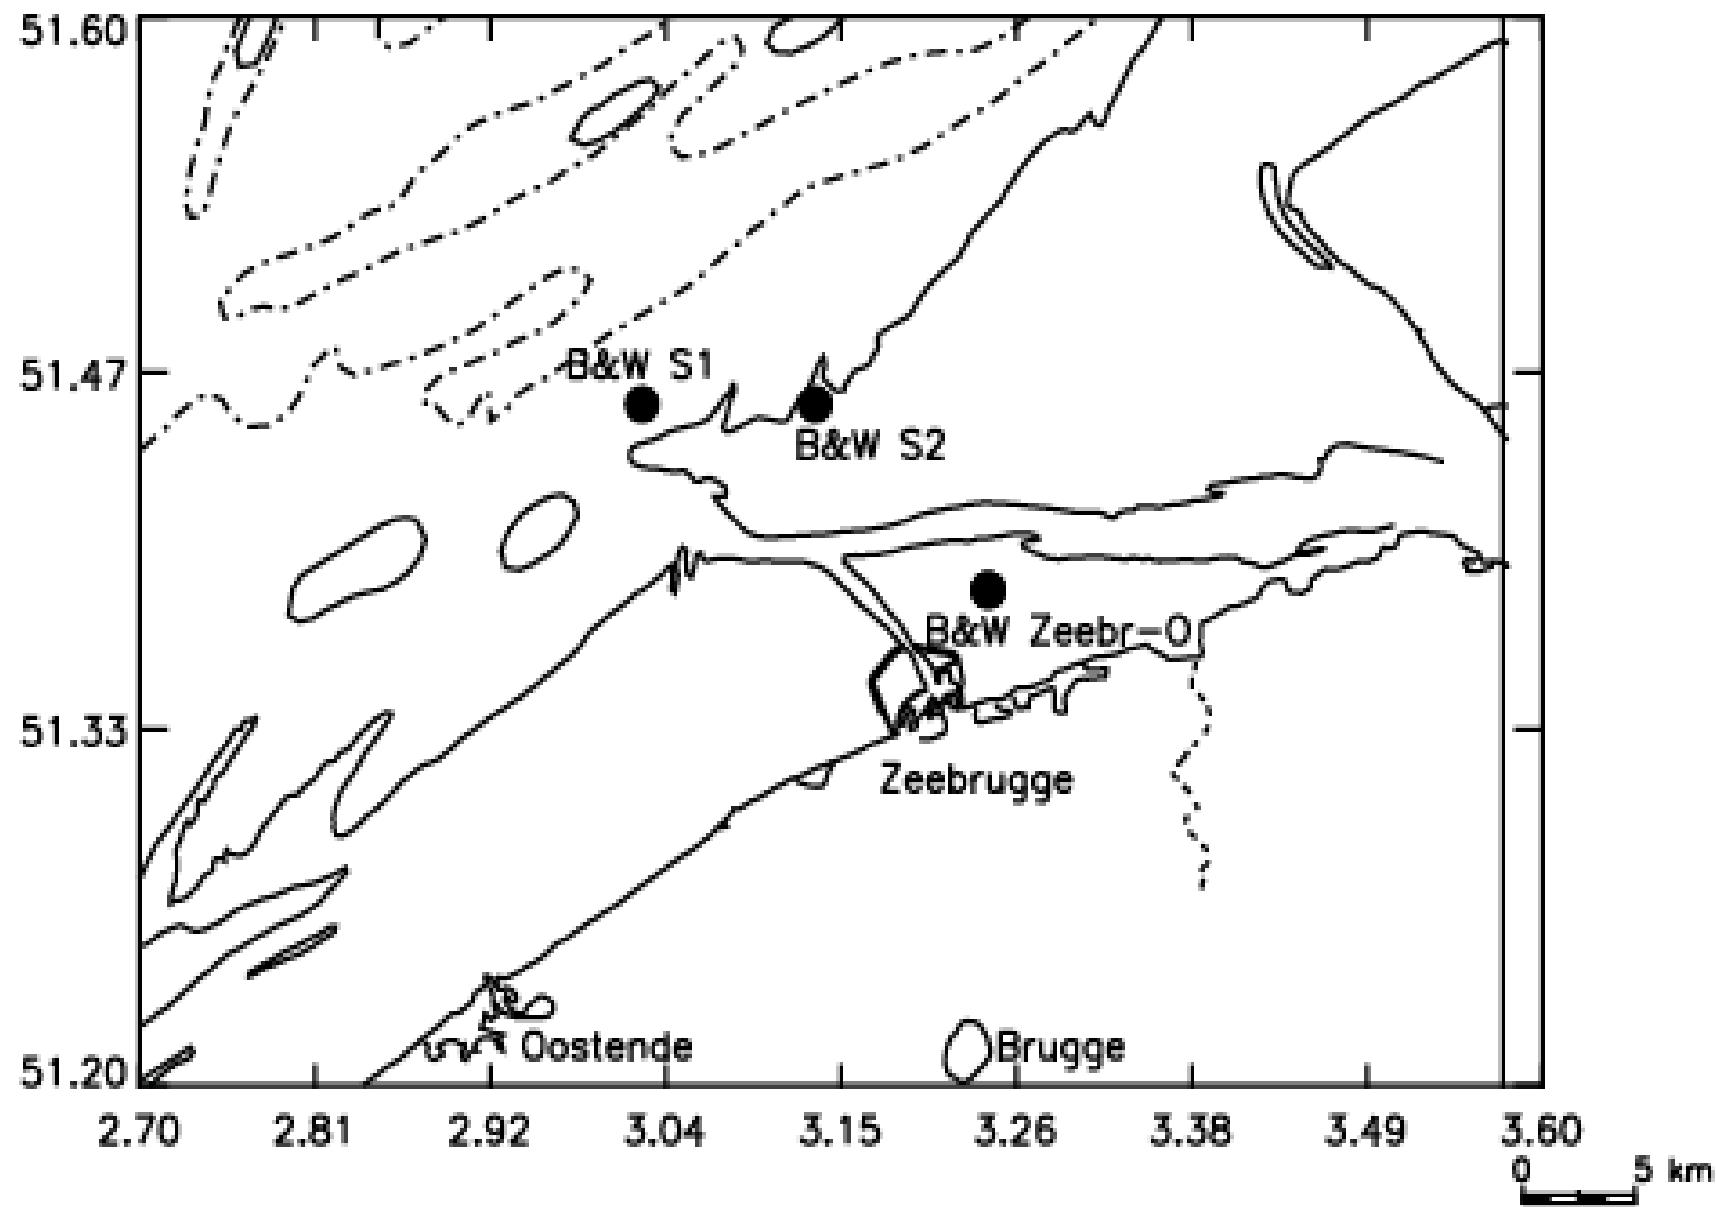

Figure 1a Dumping of dredged material in internal waters was carried out in 2000

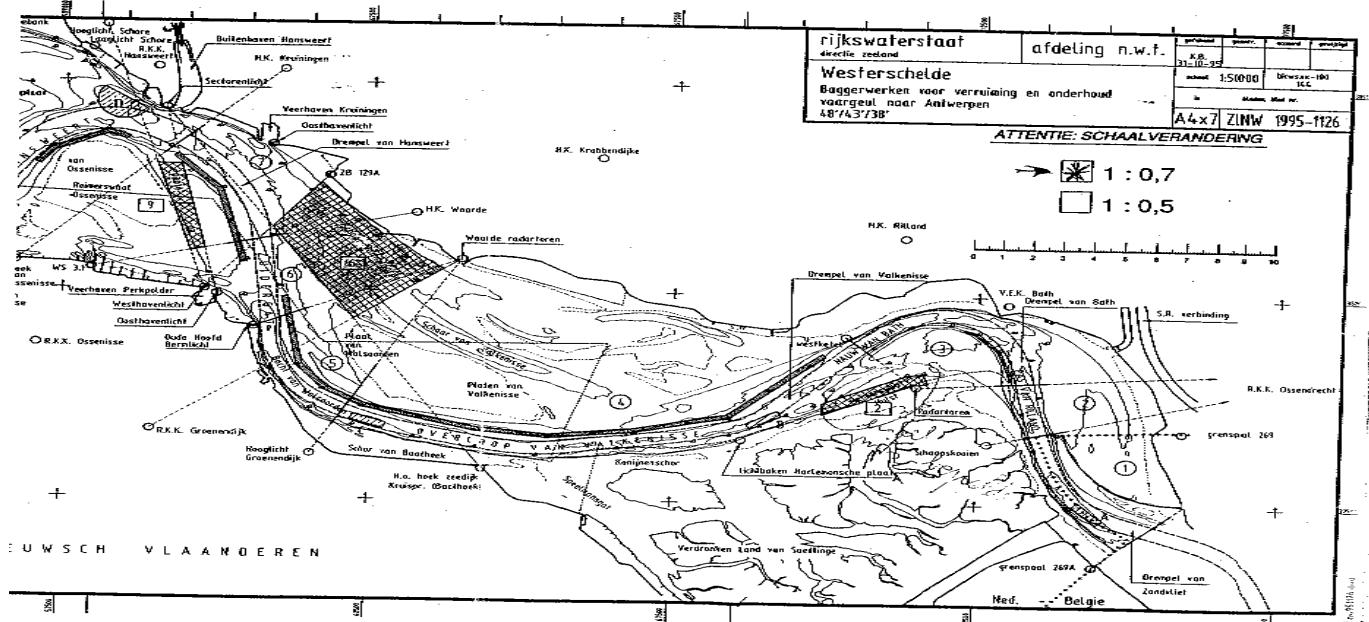

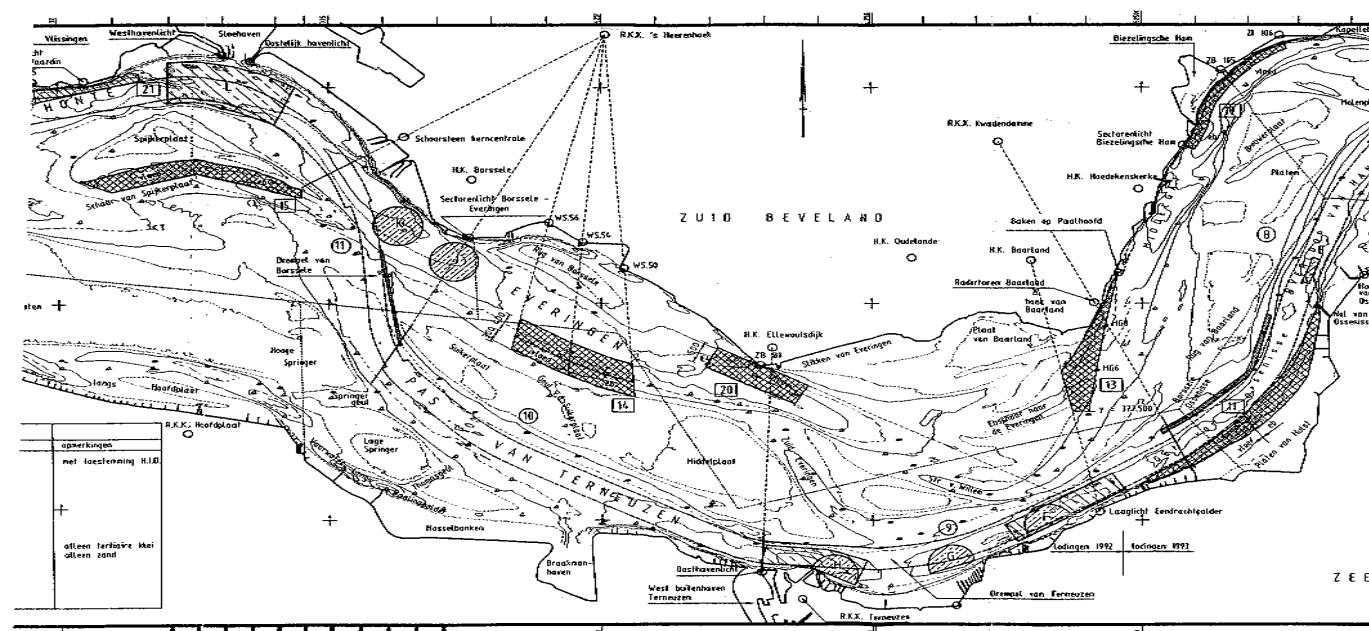

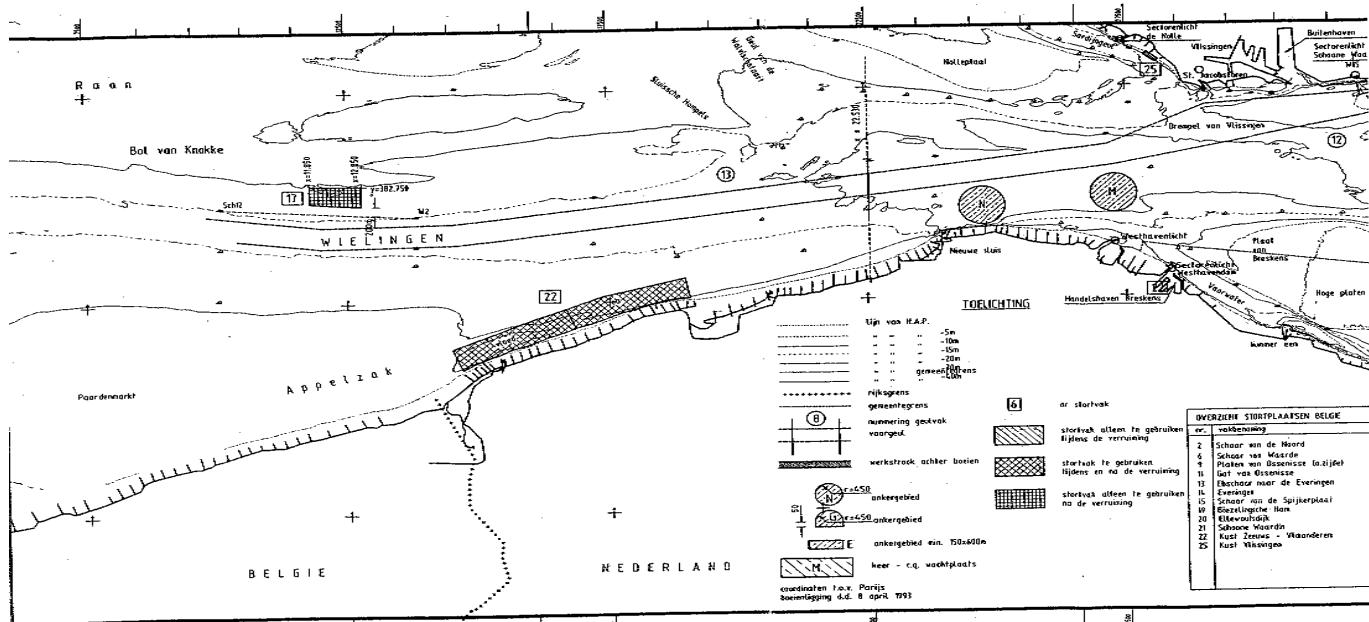

Figure 1b Dumping of dredged material in internal waters was carried out in 2000 at B/INT 0-5, 6-9

The following maps "Approximate positions of the dumping sites for dredged material used by France (Atlantic Ocean / English Channel and North Sea)", indicate the approximate positions of the dumping sites used during 2000.

Figure 2a: Approximative positions of the dumping sites for dredged material used by France in 2000
(Atlantic Ocean)
